Gluconeogenesis

(Production of glucose from noncarbohydrate precursors)

Dr. Diala Abu-Hassan

Textbook:

Lippincott's Illustrated reviews: Biochemistry

Glucose Synthesis is Required for Survival

- Brain is dependent on glucose 120g/day
- Body glucose reserve is limited

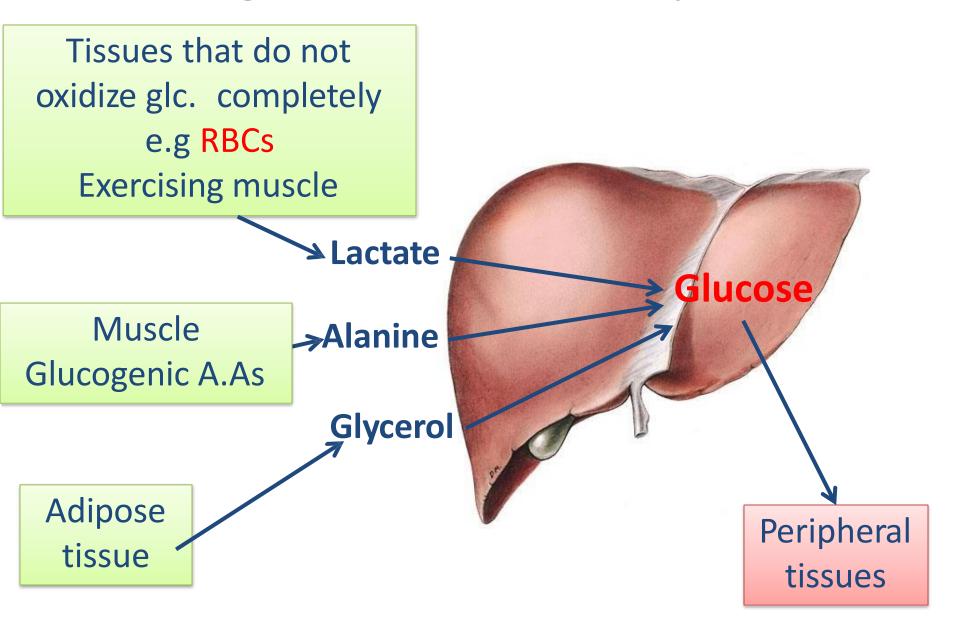

```
≈ 20 g (extra cellular fluid)
```

- ≈ 75 g (liver glycogen); enough for 16 hours
- ≈ 400 g (muscle glycogen); for muscle use only

Main source of energy for resting muscle in post-absorptive state

- 70 Kg man has ≈ 15 Kg fat
 - Fatty acids can not be converted to glucose
 - Utilization of FA is increased 4-5 X in prolonged fasting
 - In prolonged fasting; FA → ketone bodies at high rate

Gluconeogenesis occurs mainly in the liver

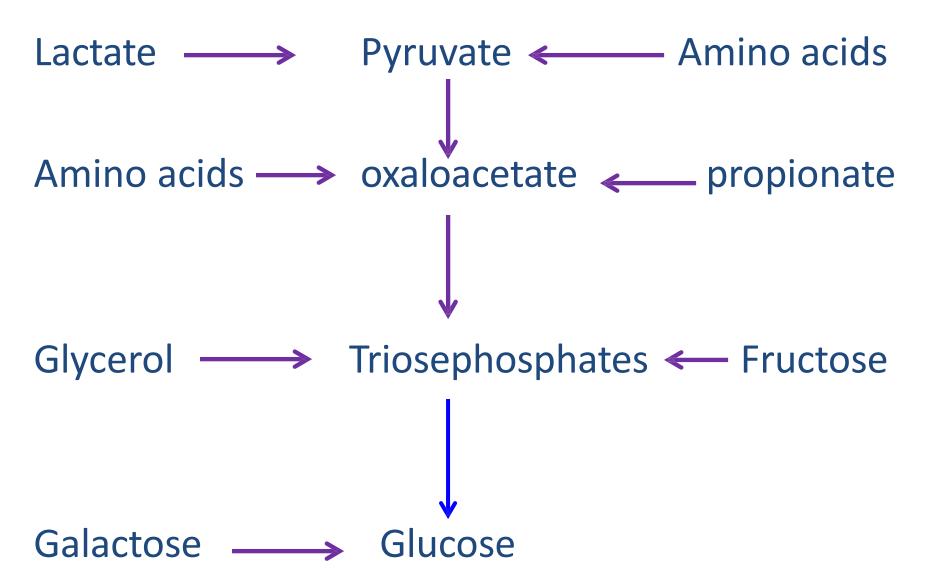

Where and when does gluconeogenesis occur?

 During an overnight fast, ~ 90% of gluconeogenesis occurs in the liver and 10% by the kidneys

 During prolonged fasting kidneys become major glucose-producing organs (40% of total glucose production)

Entrance of substrates into gluconeogenesis

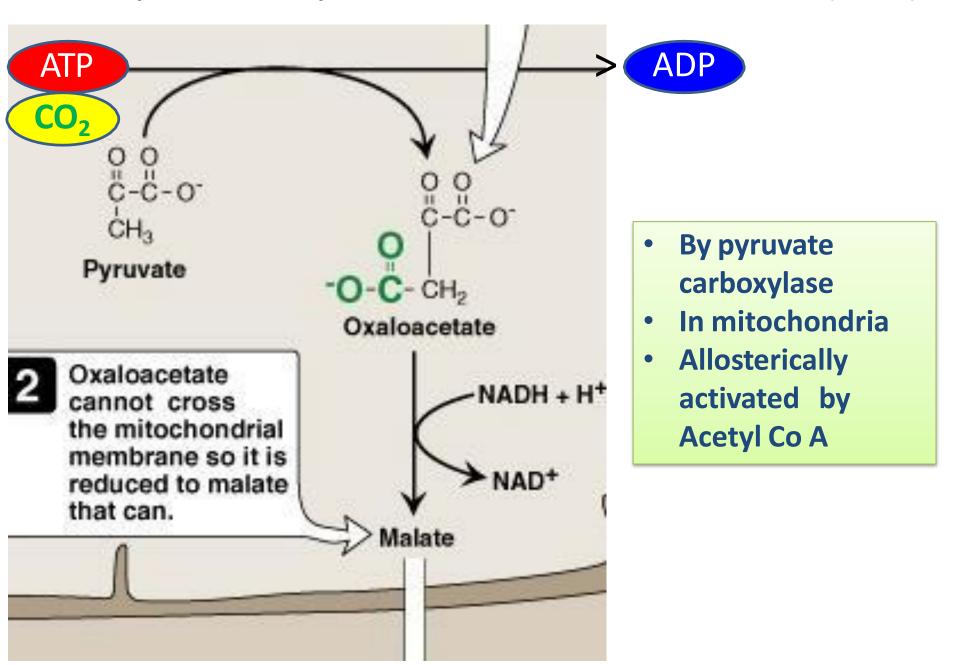

Gluconeogenesis is the opposite of glycolysis BUT

Reversing the irreversible steps

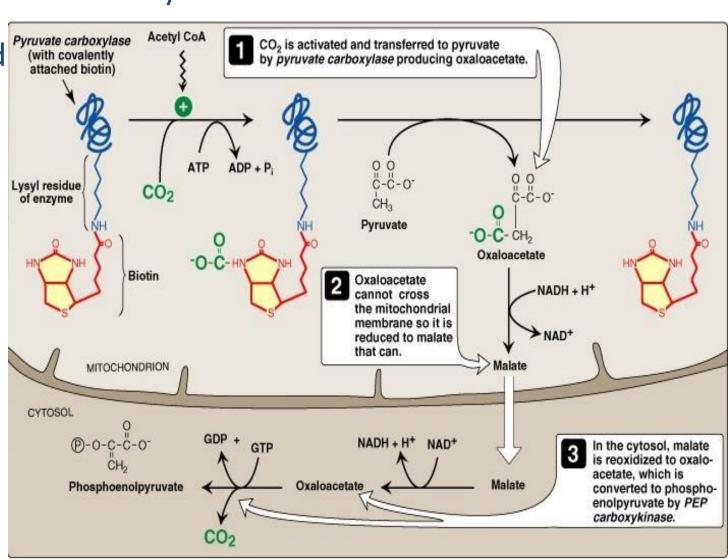

1. From pyruvate to phosphoenolpyruvate (PEP)

Carboxylation of Pyruvate Produces Oxaloacetate (OAA)

From OAA to PEP

- Enzyme is found in both cytosol and mitochondria
- PEP in the mitochondria is transported to the cytosol by a specific transporter
- The PEP that
 is generated
 in the cytosol
 requires the
 transport of

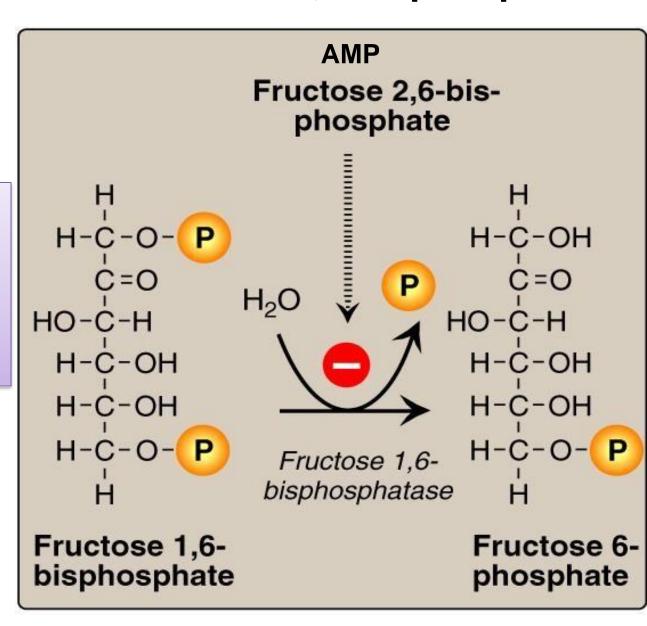

OAA from the mitochondria to the cytosol

Reversing the irreversible steps

2. From fructose-1,6-bisphosphate to fructose-6-phosphate

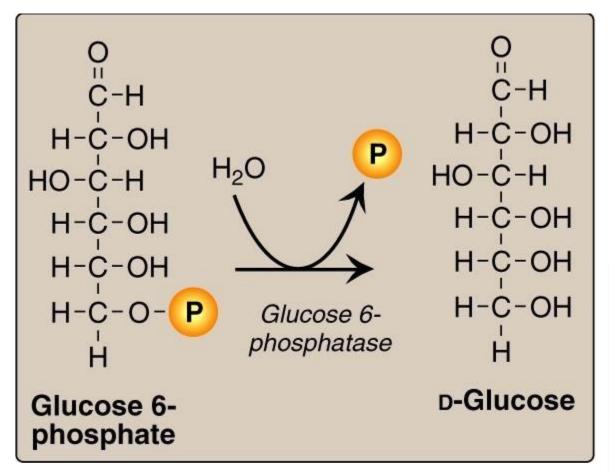

Dephosphorylation of fructose 1,6-bisphosphate

This reaction
bypasses the
irreversible
phosphofructokinase
-1 reaction

Reversing the irreversible steps

3. From glucose-6-phosphate to glucose

Glucose 6-phosphatase in Endoplasmic Reticulum (ER)

Dephosphorylation of glucose 6phosphate

- Bypasses the irreversible hexokinase reaction
- Only in liver and kidney
- Glucose 6-phosphate translocase is needed to transport G-6-P across the ER membrane

Hint: Muscle lacks glucose 6-phosphatase, and therefore muscle glycogen can not be used to maintain blood glucose levels.

Formation vs. Hydrolysis of Glucose 6phosphate

Formation

Glc. + Pi
$$\longrightarrow$$
 Glc. 6-phosphate + H₂O Δ G = +ve ATP + H₂O \longrightarrow ADP + P_i Δ G = -ve

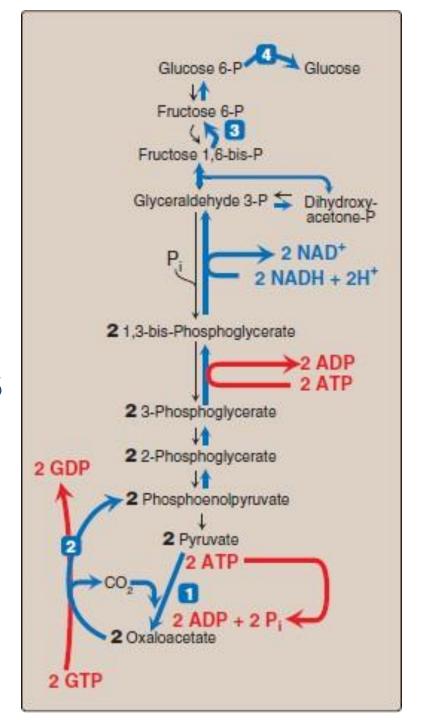

Hexokinase

Glc. + ATP
$$\longrightarrow$$
 Glc. 6-phosphate + ADP $\triangle G = -ve$

• Hydrolysis Phosphatase

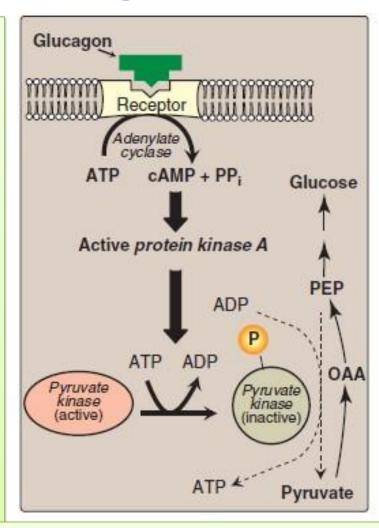

Glc. 6-phosphate + $H_2O \longrightarrow Glc. + P_i \quad \Delta G = -ve$

Energy requirements of gluconeogenesis

Regulation of gluconeogenesis

- Mainly by:
- 1. The circulating level of glucagon
- Glucagon lowers the level of fructose
 2,6-bisphosphate, resulting in
 activation of fructose 1,6 bisphosphatase and inhibition of PFK 1
- Inhibition of pyruvate kinase
- Glucagon increases the transcription of the gene for PEP-carboxykinase
- 2. The availability of gluconeogenic substrates

3. Slow adaptive changes in enzyme activity due to an alteration in the rate of enzyme synthesis or degradation, or both
