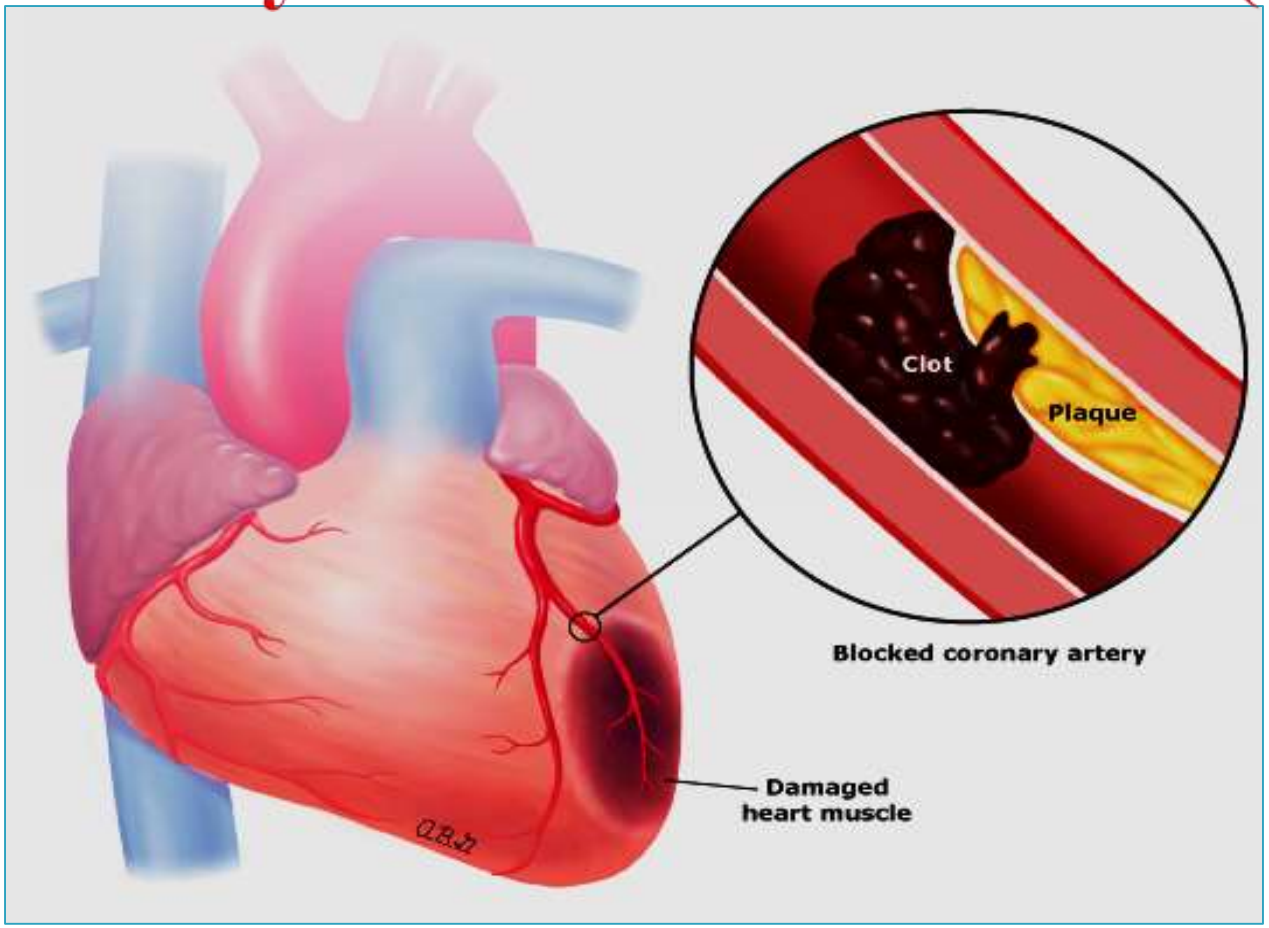
ISCHEMIC HEART DISEASE-2

Acute Myocardial Infarction

Dr. Nisreen Abu Shahin
Associate Professor of Pathology
Pathology Department
University of Jordan

Acute Myocardial Infarction (MI)



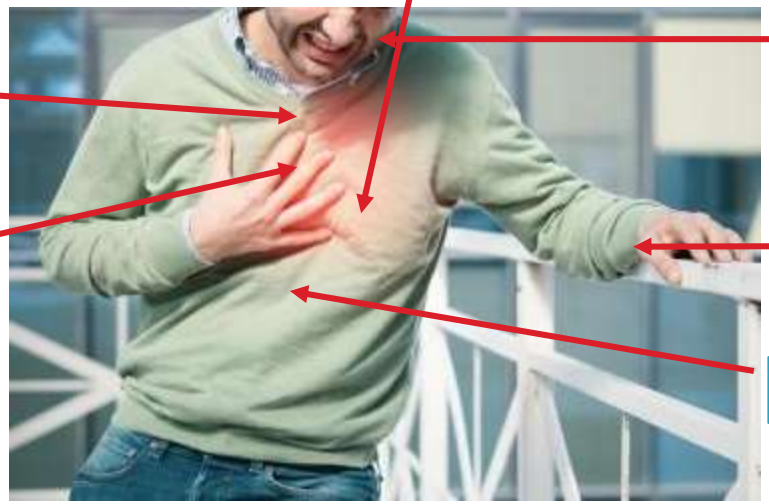
- MI = *heart attack.*
- *Necrosis of heart muscle due to ischemia.*
- A significant cause of death worldwide.

Clinical Features of acute MI

Severe, crushing substernal chest pain that radiates to neck, jaw, epigastrium, or left arm

dyspnea (if pulmonary congestion and edema)

cardiogenic shock (in massive MIs >40% of left ventricle)



Dizziness; sweating

rapid and weak pulse

nausea (in posterior MI)

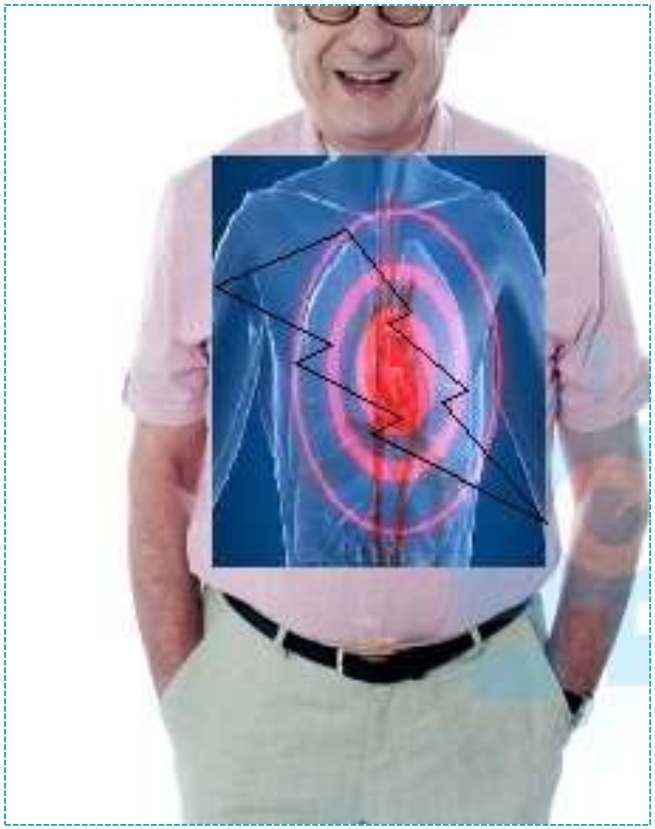
Sometimes: No typical symptoms (silent infarcts)

Silent infarcts:

- A variable percentage of MIs are asymptomatic
- Confirmed only on ECG and lab workup.
- particularly in:

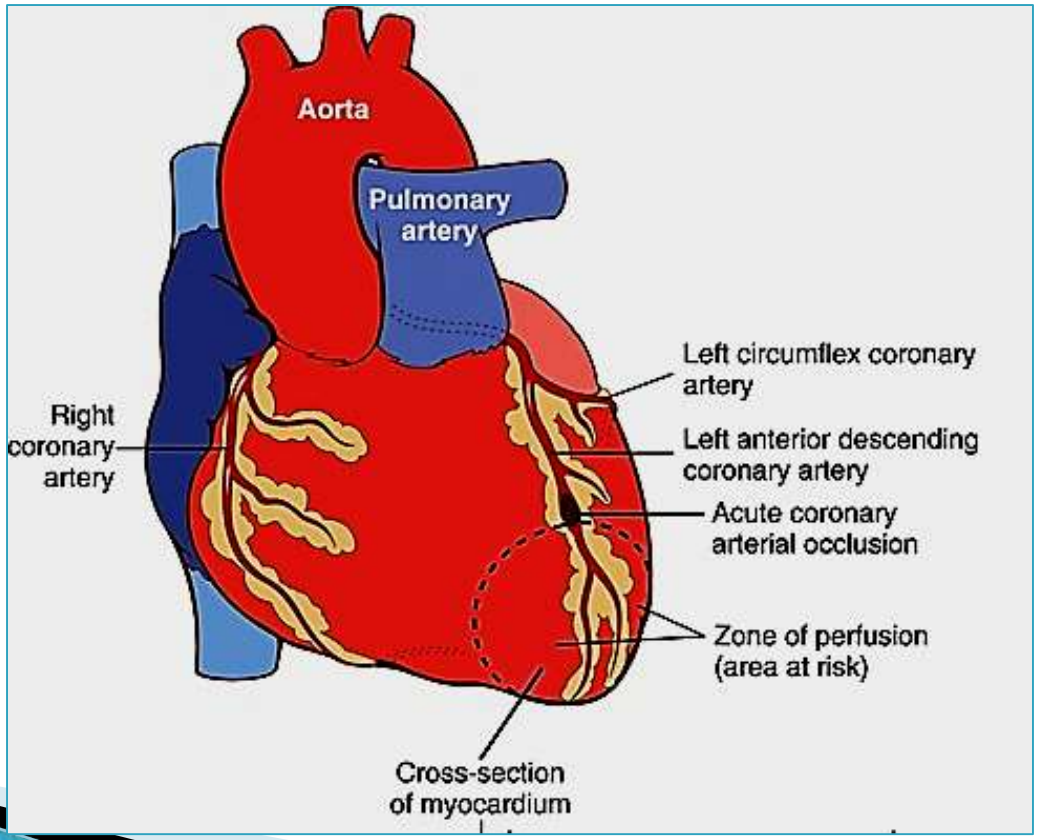
1- DM (peripheral neuropathies)

2- the elderly

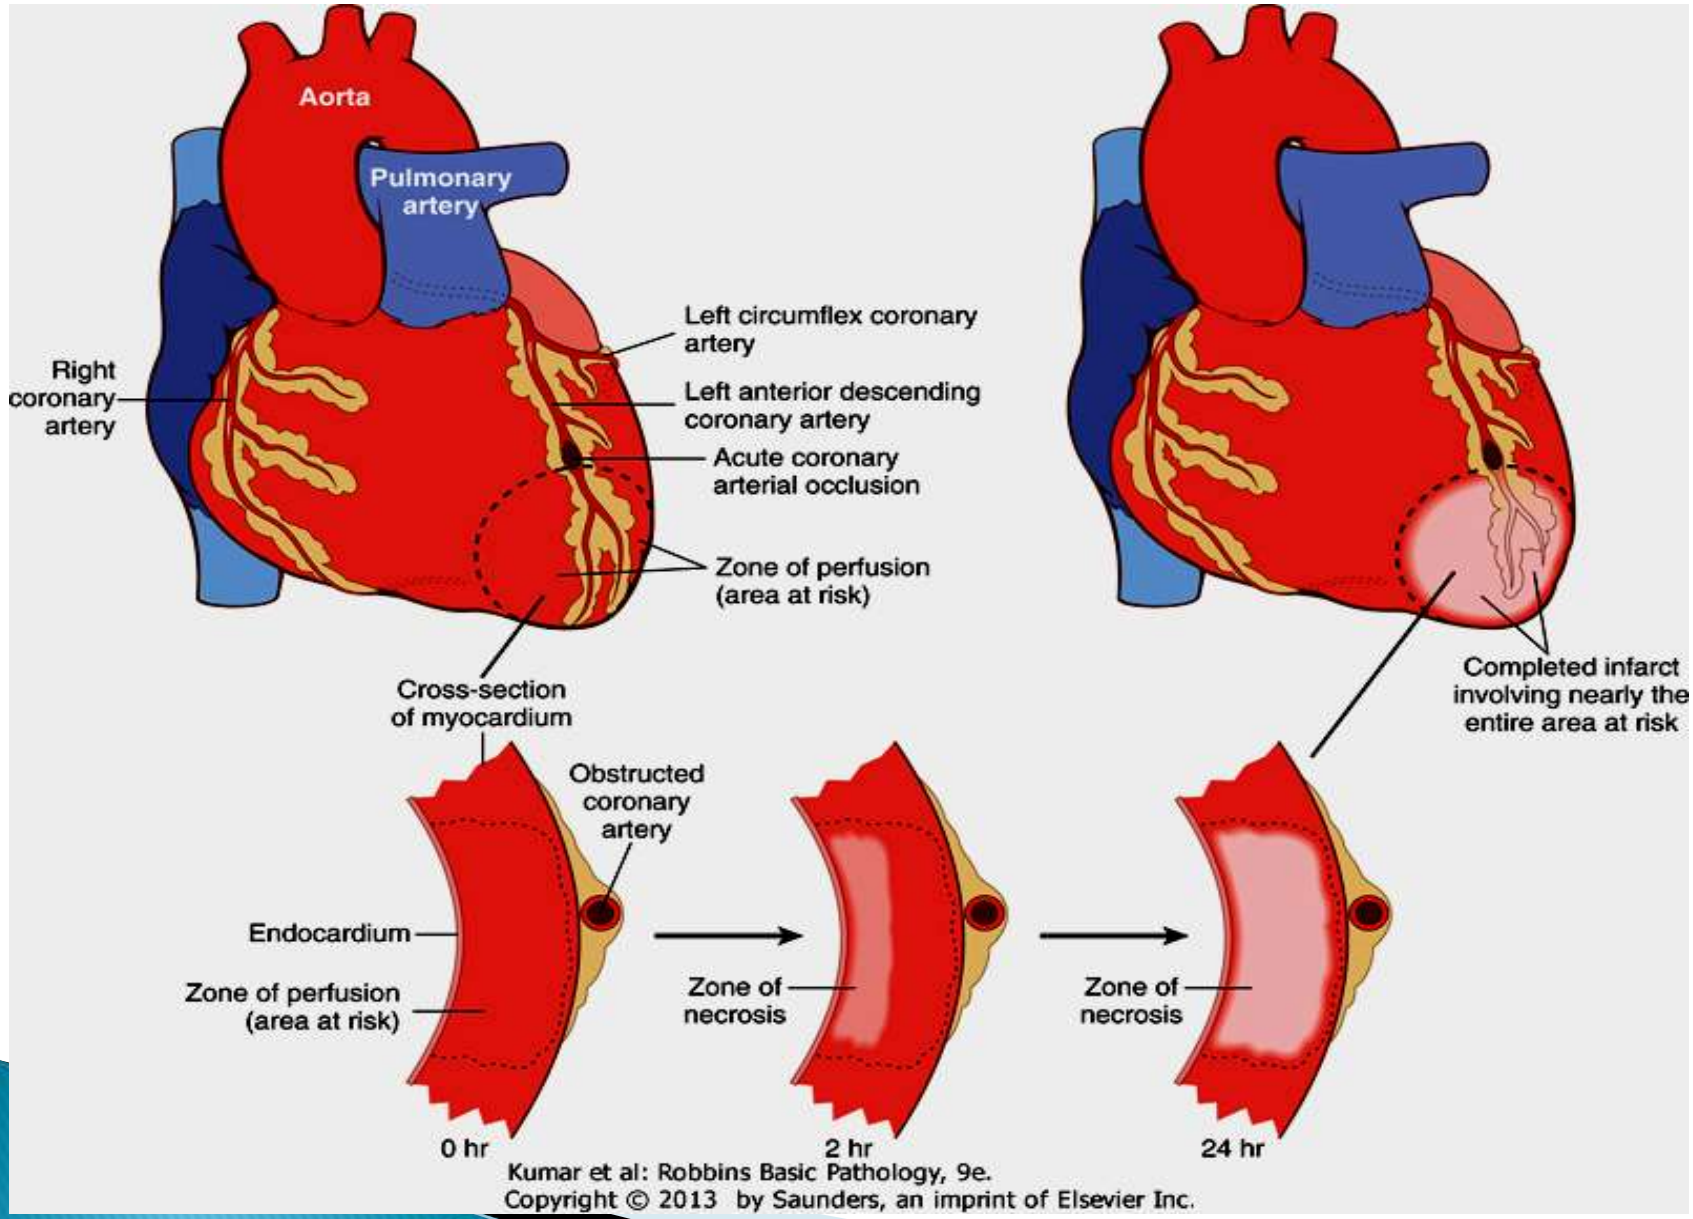


MI- Causes:

- Acute occlusion of the proximal left anterior descending (**LAD**) artery is the cause of *40% to 50% of all MI cases*

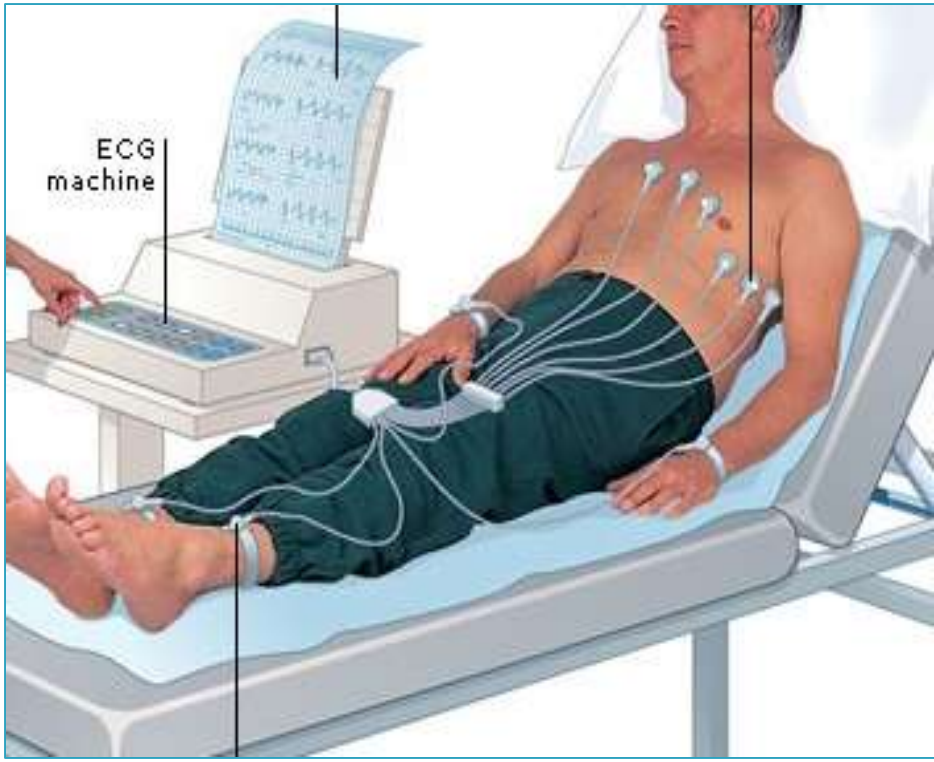


MI- Evolution



Evaluation of MI

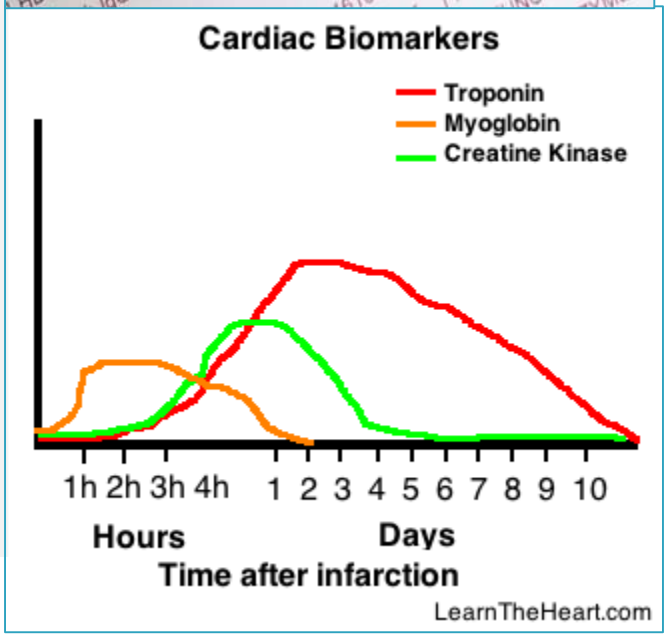
- *Clinical signs and symptoms*
- ***Electrocardiographic (ECG)** abnormalities*
- ***Laboratory evaluation:*** blood levels of intracellular macromolecules that leak out of injured myocardial cells through damaged cell membranes.



Cardiac enzymes in MI

1-Myoglobin
2-Cardiac **Troponins** T and I (TnT, TnI)
3-Creatine kinase (CK); specifically the myocardial-specific isoform (CK-MB)
4- Lactate dehydrogenase

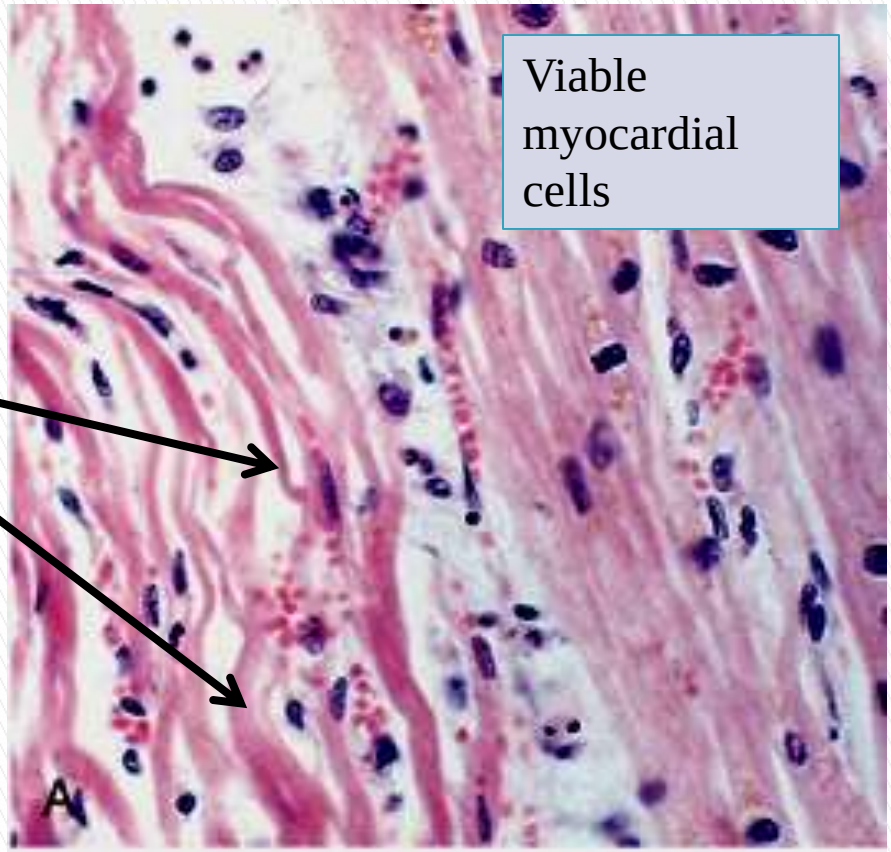
- Cardiac troponins T and I (TnT, TnI), are the best markers for acute MI.
- Creatine kinase CK-MB is the second best marker after the cardiac-specific troponins.



Microscopic features of myocardial infarction and its repair.

<24 hr:

coagulative **necrosis** and **wavy fibers** Necrotic cells are separated by edema fluid

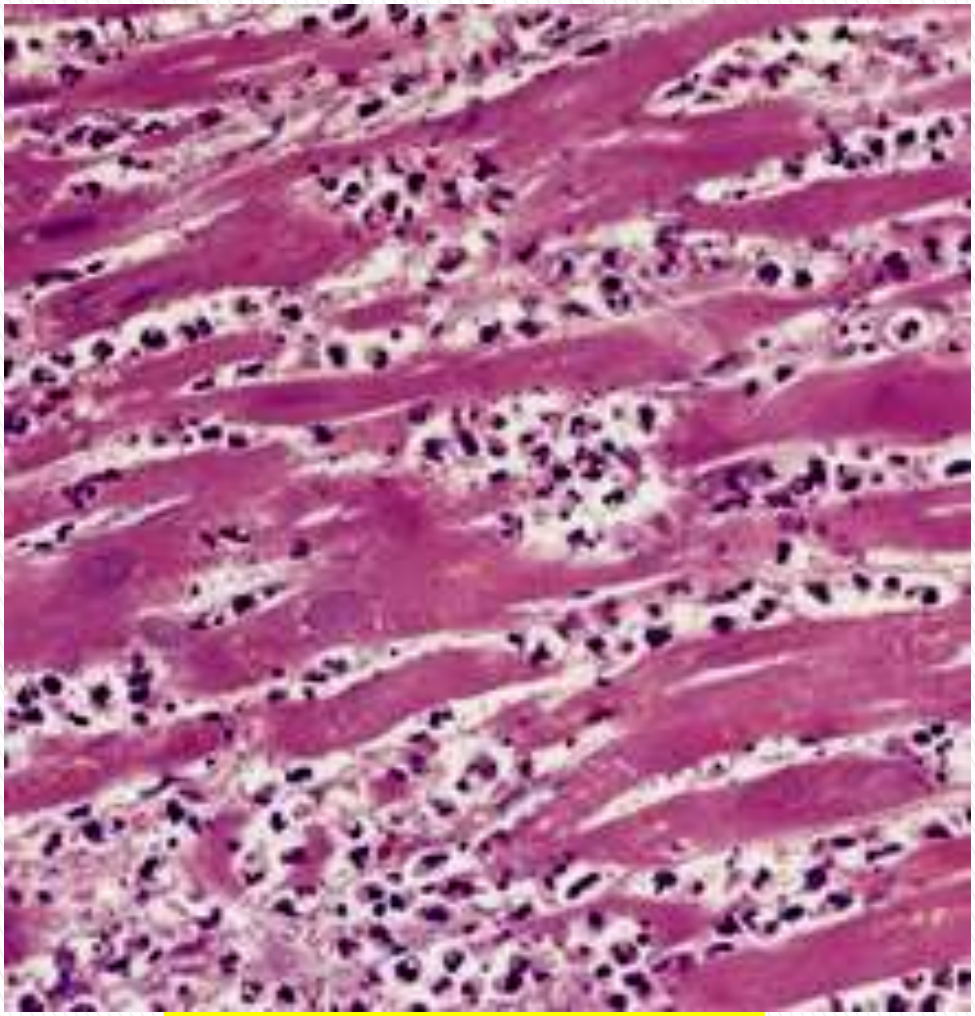


Stain: Hematoxylin & Eosin (H&E)

Microscopic features of myocardial infarction and its repair.

2 - 3 days:

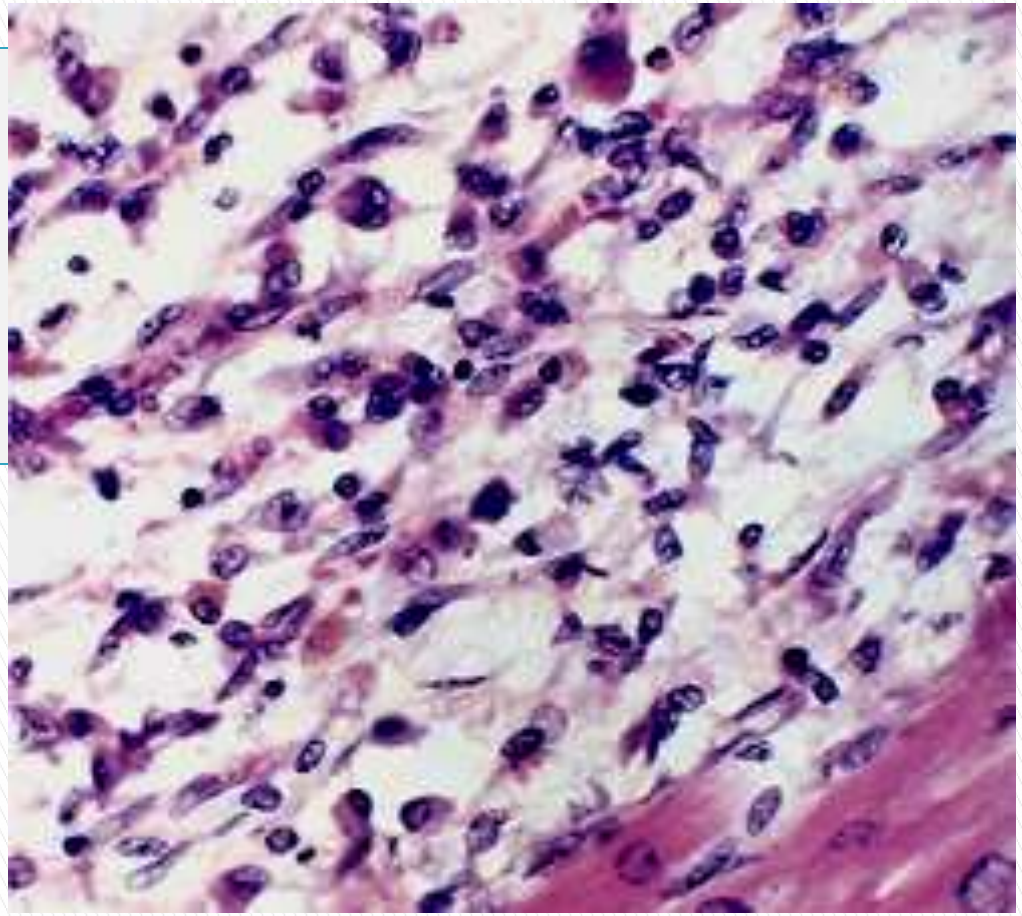
Dense **neutrophil** infiltrate



Stain: Hematoxylin & Eosin (H&E)

Microscopic features of myocardial infarction and its repair.

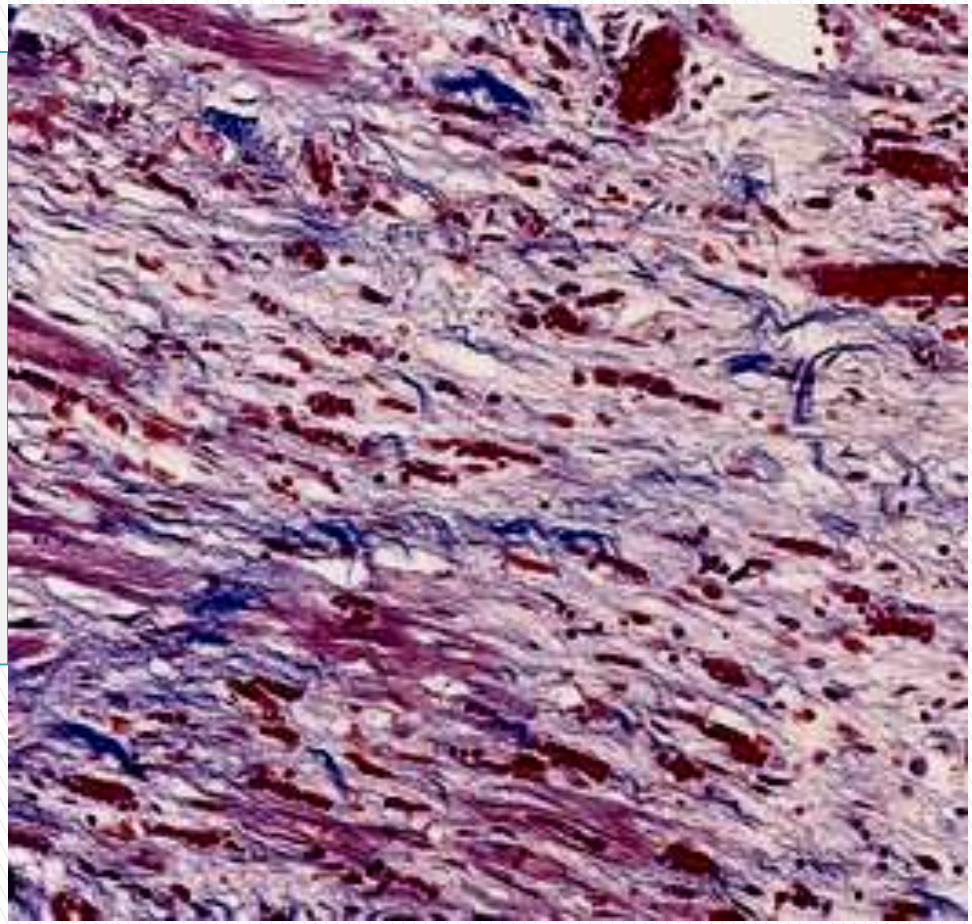
7 to 10 days:
complete removal of necrotic myocytes by **macrophages**



Stain: Hematoxylin & Eosin (H&E)

Microscopic features of myocardial infarction and its repair.

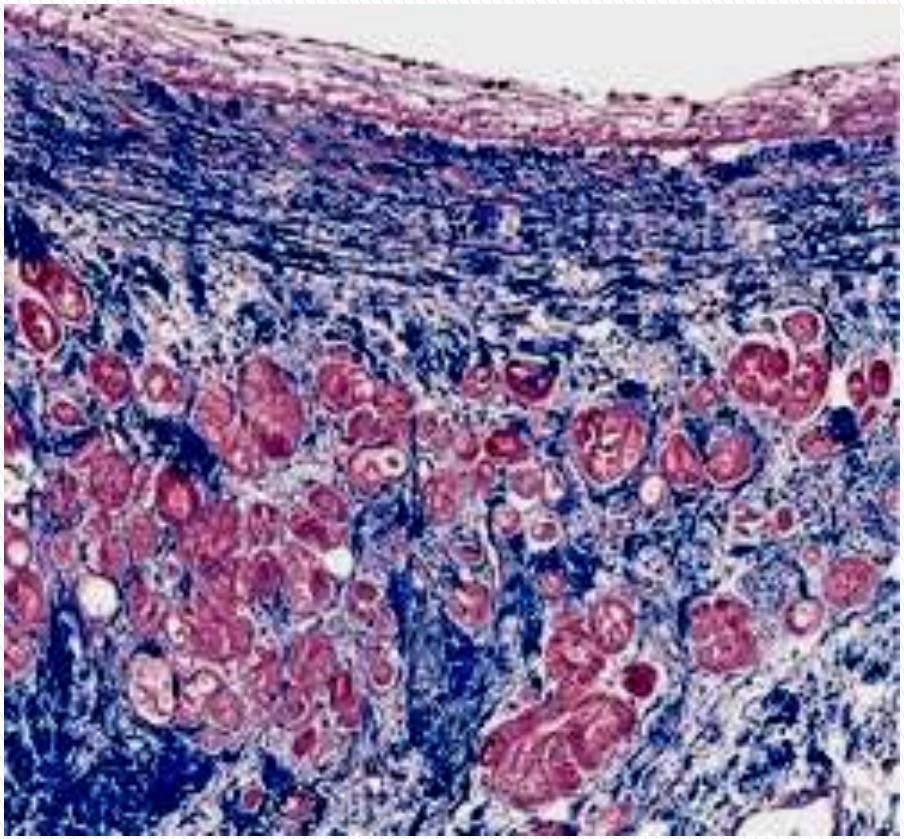
up to 14 days:
Granulation tissue
[loose connective tissue (blue) and abundant capillaries (red)]



Stain: Masson Trichrome (MT)

Microscopic features of myocardial infarction and its repair.

several weeks:
Healed infarct consisting of a dense collagenous **scar (blue)**



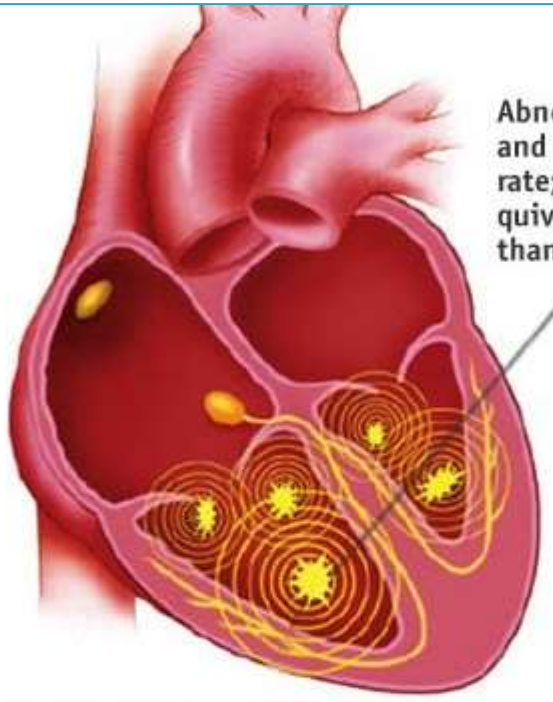
Stain: Masson Trichrome (MT)

Consequences & Complications of MI

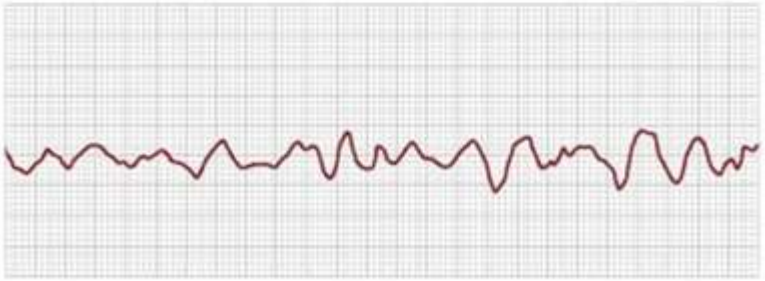
1- Death:

- **50%** occur before reaching hospital (within 1 hour of symptom onset-usually as a result of lethal arrhythmias (Sudden Cardiac Death)

- **Arrhythmias are caused by electrical abnormalities of the ischemic myocardium and conduction system**
- With current medical care, patient outcome is better (*in-hospital death rate* has declined).



Ventricular Fibrillation ECG



Consequences & Complications of MI

- ***2- Cardiogenic shock.***
- 15% - In large infarcts (>40% of Left ventricle).
- 70% mortality rate - important cause of in-hospital deaths.
- ***3-Myocardial rupture***
- ***4-Pericarditis***
- ***5-Infarct expansion***
- ***6- Mural thrombus***
- ***7-Ventricular aneurysm***
- ***8-Progressive late heart failure***

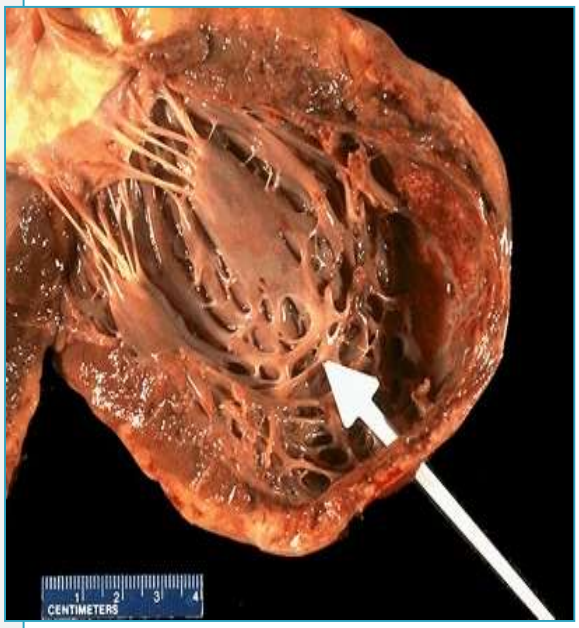
Complications of Myocardial Rupture Include:

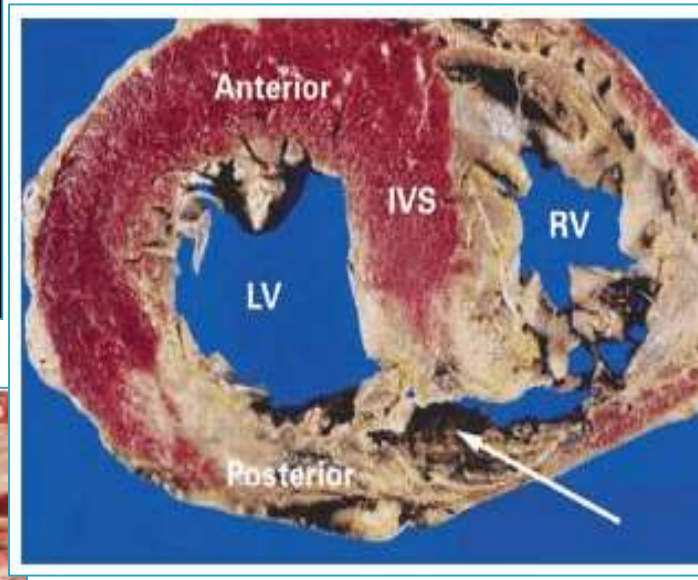
(1) rupture of the ventricular free wall: hemopericardium and cardiac tamponade (usually fatal)

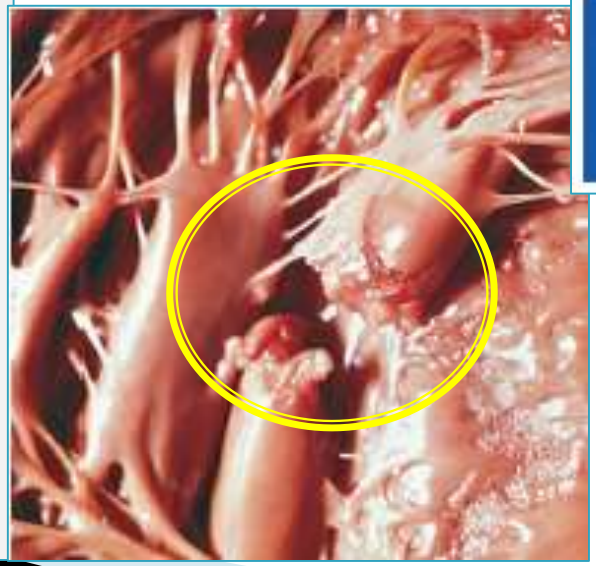
(2) rupture of the ventricular septum: VSD and left-to-right shunt

(3) papillary muscle rupture:

severe mitral or tricuspid regurgitation







4-Pericarditis.

- 2 to 3 days post a transmural MI
- spontaneously resolves (immunologic mechanism)

5-Infarct expansion.

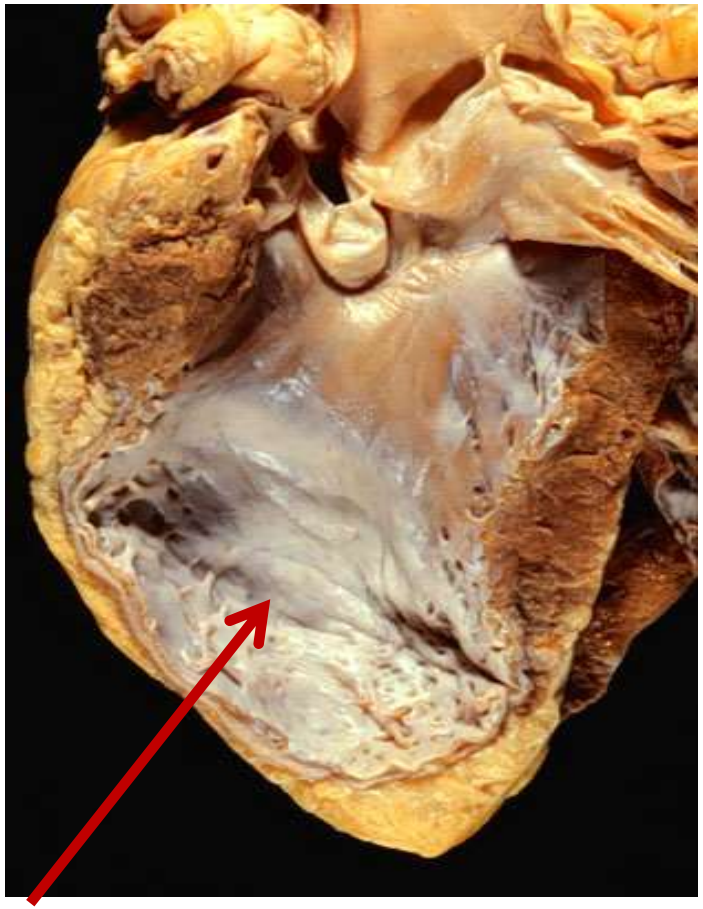
disproportionate stretching, thinning, and dilation of the infarct region (especially with anteroseptal infarcts)

6-Mural thrombus.

loss of contractility (causing stasis) + endocardial damage → ***thromboembolism***

7-Ventricular aneurysm.

- A late complication
- most commonly result from a large transmural anteroseptal infarct that heals with the formation of thin scar tissue



Complications of ventricular aneurysms include:

1-mural thrombus
2-arrhythmias
3-heart failure

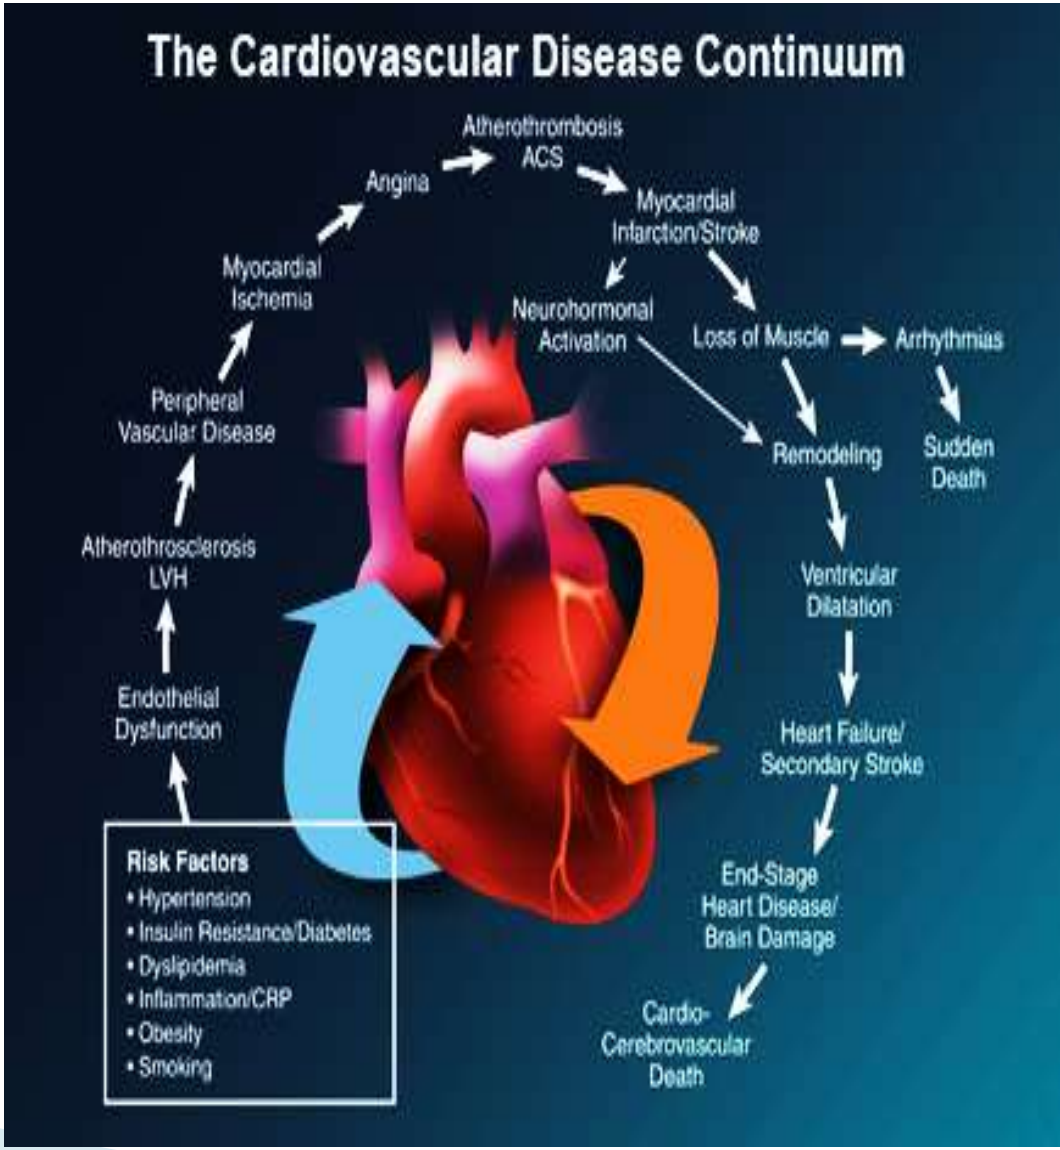
Long-term prognosis after MI

- depends on many factors: e.g. left ventricular function; severity of atherosclerosis in viable myocardium; etc...

- 1^{st} year mortality ≈ 30%.
- Thereafter, the annual mortality rate≈ 3%

Chronic Ischemic Heart Disease

- results from **post-infarction** cardiac decompensation that follows exhaustion of hypertrophic viable myocardium.
- **progressive heart failure**
- sometimes punctuated by episodes of angina or MI
- Arrhythmias are common



Sudden Cardiac Death (SCD)

- **Unexpected death from cardiac causes either without symptoms or < 24 hours of symptom onset**
- **CAD (atherosclerosis) is the most common underlying cause**
- **Lethal arrythmias (v. fibrillation) is the most common direct mechanism of death**
- With **younger** victims, other **non-atherosclerotic** causes are more common:

Non-atherosclerotic causes of SCD

- Congenital coronary arterial abnormalities
- Aortic valve stenosis
- Mitral valve prolapse
- Myocarditis
- Dilated/ hypertrophic cardiomyopathy
- Pulmonary hypertension
- Hereditary/ acquired abnormalities of cardiac conduction system
