

L.1+2: HEMEOSTASIS OF ELECTROLYTES:

- ✓ Changes in extracellular K<sup>+</sup> must not exceed ±0.3 mEq/L to avoid hypo- or hyperkalemia.
- ✓ Normal daily K<sup>+</sup> intake is about 100 mEq. This intake must be balanced to maintain K<sup>+</sup> homeostasis.

1. Exchange Between Compartments (First line regulation):

**Redistribution:** Fast transfer of K<sup>+</sup> from ECF to ICF to lower blood K<sup>+</sup> levels.

Factors That Shift K <sup>+</sup> Into Cells (Decrease Extracellular [K <sup>+</sup> ])	Factors That Shift K <sup>+</sup> Out of Cells (Increase Extracellular [K <sup>+</sup> ])
<ul style="list-style-type: none"> <li>• <b>Alkalosis:</b> Stimulates <u>Na<sup>+</sup>/K<sup>+</sup> pump</u>, moving more K<sup>+</sup> intracellularly.</li> <li>• <b>Aldosterone</b></li> </ul>	<ul style="list-style-type: none"> <li>• <b>Cell Lysis and Hyperosmolarity:</b> Lead to K<sup>+</sup> leakage from cells.</li> <li>• <b>Strenuous Exercise and β-blockers:</b> Increase hyperkalemia risk.</li> <li>• <b>Acidosis:</b> <u>Inhibits Na<sup>+</sup>/K<sup>+</sup> pump</u>, reducing K<sup>+</sup> entry into cells.</li> </ul>

2. Renal Control of Potassium:

- **PCT:** R. 65%
- **THICK.A LOH:** R. 27%
- **LDT & CD:** the end S. 12%

➤ Primary modulation occurs in the late distal tubules and collecting ducts.

**principal cells:** Secrete K<sup>+</sup> in two steps: uptake by Na<sup>+</sup>/K<sup>+</sup> pump and passive diffusion into tubular fluid.

↑ **k<sup>+</sup> secretion:** aldosterone, ↑ Na<sup>+</sup> delivery, ↑ extracellular k<sup>+</sup>

- K<sup>+</sup> secretion responds rapidly and significantly when levels exceed 4.1 mEq/L
- even small ↑ of extracellular K<sup>+</sup> → ↑ Aldosterone → ↑ k<sup>+</sup> secretion → small changes in plasma k<sup>+</sup> concentrations throughout the different intakes.
- **Aldosterone System blocked** → extreme hypo- or hyperkalemia.
- **Flow Rate:** Higher flow rates increase K<sup>+</sup> secretion, more significant with higher K<sup>+</sup> intake.
- **Diuretics that ↓ Prox. Or ↓ Loop Na + Reabsorption:** ↑ tubular fluid flow rate → ↑ K<sup>+</sup> secretion → K<sup>+</sup> depletion

➤ **Sodium (Na<sup>+</sup>) Intake and Potassium (K<sup>+</sup>) Secretion:**

Effects of Increased Na<sup>+</sup> Intake:

- ↑ GFR/↓ Proximal Tubular Na<sup>+</sup> Reabsorption: ↑ tubular flow enhances K<sup>+</sup> secretion.
- ↓ aldosterone: decreases K<sup>+</sup> secretion.

Condition	Effect on Na <sup>+</sup> /K <sup>+</sup> ATPase	Effect on Intracellular K <sup>+</sup>	Effect on K <sup>+</sup> Secretion	Result
<b>Acute Acidosis</b>	Inhibits	Decreases	Reduces	Leads to hyperkalemia
<b>Chronic Acidosis</b>	-	-	Stimulates (hyperkalemia remains mild due to compensatory mechanisms)	Increases tubular flow rate and inhibits proximal NaCl and water reabsorption
<b>Alkalosis</b>	Increases	Increases	Enhances	Leads to hypokalemia

- **Hyperkalemia** is caused by factors that reduce potassium excretion or increase potassium reabsorption, (renal failure, ↓ distal nephron flow, ↓ aldosterone or its effects, metabolic **acidosis**, diabetes, and removal of prostaglandins.)
- **Hypokalemia** from factors that increase potassium excretion or uptake into cells (very low potassium intake, GI losses, metabolic **alkalosis**, excess insulin, increased distal tubular flow, and excess aldosterone or other mineralocorticoids.)

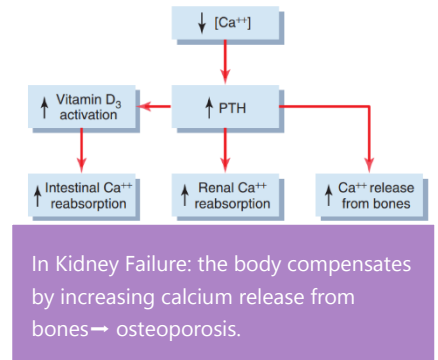

➤ **Compensatory Responses to Decreased Plasma Ionized Calcium:**

• **Proximal Tubular Calcium Reabsorption:**

1. **Paracellular Pathway:** Most of the calcium reabsorption here, calcium is dissolved in water and carried between cells.
2. **Transcellular Route:** About 20% (diffuses down by  $\text{Ca}^{++}$  ATPase and  $\text{Ca}^{++}/\text{Na}^{+}$  countercurrent transporters)

• **Thick Ascending Limb and Distal Tubule:** paracellular & transcellular (PTH effect)

○ **Integration of Renal Mechanisms for Regulation of Body Fluids and Electrolytes:**

Excretion = Filtration - Reabsorption + Secretion.

In a steady-state:  
Fluid Excretion = Fluid Intake  
Electrolyte Excretion = Electrolyte Intake

1. **Effect of Decreased GFR on Sodium:**

- $\downarrow \text{GFR} \rightarrow \downarrow \text{reabsorption} \rightarrow \text{excretion remains consistent. (+ balance)}$

2. **Maintenance of Sodium Balance after decrease reabsorption:**

- $\downarrow \text{reabsorption} \rightarrow \downarrow \text{GFR} \rightarrow \text{excretion remains consistent. (- balance)}$

L.3+4: ACID-BASE BALANCE:

- **Mechanisms of Hydrogen Ion Regulation:**

1. **Chemical Buffers (Rapid but Temporary):**

Temporarily reduce pH deviations until other systems can correct imbalances.

Buffer effectiveness depends on reactant concentrations and closeness of pH to buffer's pK.

Buffer System	Components	Location	Function
Bicarbonate most important buffer	$\text{CO}_2$ and $\text{HCO}_3^-$	Extracellular fluid (ECF)	Regulates pH by adjusting $\text{CO}_2$ and $\text{HCO}_3^-$ . Carbonic anhydrase facilitates conversion. <b>Metabolic Alkalosis:</b> $\uparrow \text{HCO}_3^-$ in urine. <b>Acidosis:</b> $\uparrow \text{H}^+$ relative to $\text{HCO}_3^-$ in urine.
Phosphate	$\text{HPO}_4^{2-}$ and $\text{H}_2\text{PO}_4^{1-}$	Renal tubular fluid	Accepts or donates $\text{H}^+$ ions to maintain pH stability.
Ammonia	$\text{NH}_3$ and $\text{NH}_4^+$	Tubular fluid	Converts excess hydrogen to ammonium ( $\text{NH}_4^+$ ) to reduce acidity, especially in chronic acidosis.
Proteins (Intracellular)	Intracellular proteins	Within cells	Intracellular buffering; follows extracellular pH deviations due to dynamic electrolyte movement.

- Kidneys and lungs regulate  $\text{CO}_2$ ,  $\text{H}^+$ , and  $\text{HCO}_3^-$  levels, optimizing bicarbonate buffer effectiveness.

2. **Respiratory System (Lungs):**

- Rapid response; eliminates  $\text{CO}_2$
- Not effective for non-volatile acids.

Acidosis Correction:	Alkalosis Correction:
<ul style="list-style-type: none"> <li>• <math>\uparrow</math> blood acidity (<math>\text{H}^+</math> concentration) triggers <math>\uparrow</math> alveolar ventilation, <math>\downarrow \text{CO}_2</math>.</li> <li>• <math>\downarrow \text{CO}_2</math> shifts the equation to the left, promoting <math>\text{HCO}_3^-</math> combination with <math>\text{H}^+</math>, <math>\downarrow \text{H}^+</math> concentration.</li> </ul>	<ul style="list-style-type: none"> <li>• <math>\downarrow</math> alveolar ventilation in alkalosis <math>\downarrow</math> removal of <math>\text{CO}_2</math>.</li> <li>• This shifts the equation towards <b>generating more <math>\text{H}^+</math></b>, counterbalancing alkalinity.</li> </ul>

3. **Urinary System (Kidneys):** Slow but powerful; eliminates non-volatile acids.

Functions: secretes  $\text{H}^+$ , reabsorbs  $\text{HCO}_3^-$ , generates new  $\text{HCO}_3^-$ .

**Proximal Tubule and Thick Loop of Henle:** minimal PH 6.7

- **Na<sup>+</sup>/H<sup>+</sup> exchanger** driven by Na<sup>+</sup>/K<sup>+</sup> ATPase reabsorbs Na<sup>+</sup> and **secreted H<sup>+</sup>**.
- H<sup>+</sup> combines with filtered HCO<sub>3</sub><sup>-</sup> to form H<sub>2</sub>CO<sub>3</sub>, which dissociates into H<sub>2</sub>O and CO<sub>2</sub>.
- CO<sub>2</sub> re-enters cells to form **more H<sup>+</sup> and HCO<sub>3</sub><sup>-</sup>**, promoting **HCO<sub>3</sub><sup>-</sup> reabsorption**.
- Each secreted H<sup>+</sup> results in one HCO<sub>3</sub><sup>-</sup> reabsorbed.

**Late Distal and Collecting Tubules (Type A Intercalated Cells):** minimal PH 4.5

- CO<sub>2</sub> combines with H<sub>2</sub>O form HCO<sub>3</sub><sup>-</sup> / H<sup>+</sup>, HCO<sub>3</sub><sup>-</sup> reabsorbed via **HCO<sub>3</sub><sup>-</sup>/Cl<sup>-</sup> exchanger**.
- **H<sup>+</sup> ATPase pump** secretes H<sup>+</sup> against a large gradient.
- **K<sup>+</sup>/H<sup>+</sup> ATPase pump** secretes H<sup>+</sup> and reabsorbs K<sup>+</sup>. (↑ activity by hypokalemia)
  - **Acidosis:** ↑ H<sup>+</sup> secretion, HCO<sub>3</sub><sup>-</sup> reabsorption, and new HCO<sub>3</sub><sup>-</sup> production.
  - **Alkalosis:** ↓ H<sup>+</sup> secretion, decreased HCO<sub>3</sub><sup>-</sup> reabsorption, and ↑ HCO<sub>3</sub><sup>-</sup> excretion.

✓ Buffers like phosphate and ammonia neutralize excess H<sup>+</sup>.  
 ✓ New HCO<sub>3</sub><sup>-</sup> is produced when H<sup>+</sup> is titrated by non-HCO<sub>3</sub><sup>-</sup> buffers.

- **The kidneys must excrete at least 60 mmol of non-volatile acids daily. Without buffers, this would require excreting 2000 liters of urine daily, which is impractical.**

In acidosis, the kidneys manage excess H<sup>+</sup> using HCO<sub>3</sub><sup>-</sup>, phosphate, and ammonia buffers. When phosphate and ammonia titrate H<sup>+</sup>, new HCO<sub>3</sub><sup>-</sup> is produced, adding extra bicarbonate to the extracellular fluid.

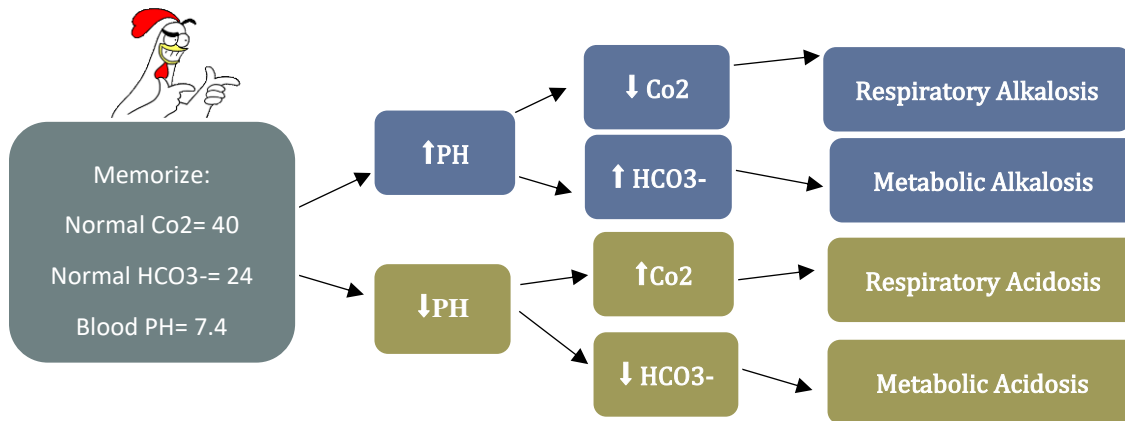

Phosphate Buffer: 6.8	Ammonia Buffer:
<p><b>Mech:</b> NaHPO<sub>4</sub><sup>-</sup> combines with H<sup>+</sup> to form NaH<sub>2</sub>PO<sub>4</sub>, titrating excess H<sup>+</sup> and maintaining urine concentration.</p> <p><b>Capacity:</b> Buffers about 30 mmol/day of H<sup>+</sup>.</p> <p><b>Not the major for C.acidosis</b></p>	<p><b>Production:</b> Glutamine metabolism produces NH<sub>4</sub><sup>+</sup> and new HCO<sub>3</sub><sup>-</sup>.</p> <p><b>Mech:</b> NH<sub>3</sub> combines with secreted H<sup>+</sup> to form NH<sub>4</sub><sup>+</sup>, which is then excreted, creating new HCO<sub>3</sub><sup>-</sup>.</p> <p><b>Ammonia production increases in acidosis, providing a significant buffering capacity.</b></p>

- **Total H<sup>+</sup> Secretion:**
  - HCO<sub>3</sub><sup>-</sup> reabsorption: 4320 mmol/day+ Titratable acid: 30 mmol/day+ NH<sub>4</sub><sup>+</sup> excretion: 30 mmol/day= **Total: 4380 mmol/day.**
- **Net H<sup>+</sup> Excretion:**
  - Titratable acid: 30 mmol/day+ NH<sub>4</sub><sup>+</sup> excretion: 30 mmol/day- HCO<sub>3</sub><sup>-</sup> excretion: 1 mmol/day= **Net Excretion: 59 mmol/day.**

**SUMMARY OF ACID-BASE DISORDERS:**

		Renal Responses	Respiratory compensation
Acidosis ↓PH	<b>Respiratory Acidosis</b> ↑ pCO <sub>2</sub>	<ul style="list-style-type: none"> <li>• Complete HCO<sub>3</sub><sup>-</sup> reabsorption+ generates new HCO<sub>3</sub><sup>-</sup>.</li> <li>• ↑ tubular H<sup>+</sup> secretion → ↑ buffers like NH<sub>4</sub><sup>+</sup> and NaHPO<sub>4</sub><sup>-</sup></li> </ul>	
	<b>Metabolic Acidosis</b> ↓ HCO <sub>3</sub> <sup>-</sup>	<ul style="list-style-type: none"> <li>• Complete HCO<sub>3</sub><sup>-</sup> reabsorption</li> <li>• ↑ secretion of H<sup>+</sup> titrated by non-HCO<sub>3</sub><sup>-</sup> buffers → generating new HCO<sub>3</sub><sup>-</sup></li> </ul>	↑ ventilation → ↓ pCO <sub>2</sub>
Alkalosis ↑PH	<b>Respiratory Alkalosis</b> ↓ pCO <sub>2</sub>	<ul style="list-style-type: none"> <li>• ↓ H<sup>+</sup> secretion</li> <li>• ↓ HCO<sub>3</sub><sup>-</sup> reabsorption, leading to excess tubular HCO<sub>3</sub><sup>-</sup> excretion</li> </ul>	
	<b>Metabolic Alkalosis</b> ↑ HCO <sub>3</sub> <sup>-</sup>	<ul style="list-style-type: none"> <li>• ↑ HCO<sub>3</sub><sup>-</sup> filtration</li> <li>• ↓ H<sup>+</sup> secretion, resulting in excess tubular HCO<sub>3</sub><sup>-</sup> and increased excretion</li> </ul>	↓ ventilation → ↑ pCO <sub>2</sub>

NOTE: SOMETIMES WE MIGHT HAVE MIXED ACIDOSIS OR MIXED ALKALOSIS

### Anion Gap as a Diagnostic Tool

$$\text{Anion Gap} = \text{Na}^+ - (\text{Cl}^- + \text{HCO}_3^-)$$

Normal: 8-16 mEq/L

- helps differentiate **between types of metabolic acidosis** by revealing whether there is an accumulation of unmeasured anions or a simple loss of bicarbonate with a corresponding rise in chloride.
- **High Anion Gap Acidosis** suggests conditions like **diabetic ketoacidosis or lactic acidosis**.
- **Normal Anion Gap Acidosis** indicates conditions like **diarrhea or renal tubular acidosis**. (GI) hyperchloremia

↓ extracellular volume → ↑ Ang2, aldosterone → ↓ K+ ↑ H+ / pump → ↑ H+ secretion → metabolic alkalosis
