**JORDAN**

# ***Respiratory Failure***

Dr. Ahmad Arraqap

Anesthesia dept.

Faculty of Medicine

Jordan University

- **Definition and Classification**
- **Etiology**
- **Pathophysiology**
- **Clinical Presentation**
- **Diagnosis**
- **Management**

- The respiratory system provides oxygen to and removes carbon dioxide from the body.
- the inability to perform either or both of these tasks results in respiratory failure

- Respiratory failure occurs when the respiratory system fails to maintain adequate gas exchange, resulting in abnormal blood levels of oxygen (O<sub>2</sub>) and carbon dioxide (CO<sub>2</sub>).
- It is a clinical syndrome characterized by an inability to meet the metabolic demands of the body for oxygen and/or the removal of carbon dioxide.
- This failure can be either acute or chronic,
- It can be classified based on the primary gas exchange disturbance (hypoxemia and/or hypercapnia)

- Respiratory failure is a syndrome that develops when the respiratory system is unable to maintain **oxygenation and/or VENTILATION**

- **Oxygenation** — Oxygenation is the process of oxygen diffusing passively from the alveolus to the pulmonary capillary, where it mostly binds to hemoglobin in red blood cells (oxyhemoglobin); a small proportion directly dissolves into the plasma.
- **Oxygen delivery** — Oxygen delivery is the rate of oxygen transport from the lungs to the peripheral tissues.
- **Oxygen consumption** is the rate at which oxygen is removed from the blood for use by the tissues.
- **Hypoxemia** — Hypoxemia is defined by an arterial oxygen tension  $<60$  mmHg (ie, insufficient oxygenation). Hypoxemia does not necessarily always indicate tissue hypoxia.
- **Hypoxia** — Hypoxia is defined as a condition where the oxygen supply is inadequate either to the body as a whole (general hypoxia) or to a specific region (tissue hypoxia). Hypoxia can be due to reduced oxygen delivery and/or increased oxygen consumption by tissue.

# Respiratory system function depends on :

- CNS control.
- Neuromuscular function.
- Upper airway muscles and reflexes.
- Thorax and pleura.
- Alveolar function.

FIGURE 10.16. A Schematic Representation of the Regulation of Respiration

# CLASSIFICATION

- **The time course:**
  - Acute respiratory failure: occurs within minutes to hours of an inciting incident.
  - Chronic respiratory failure:
    - Occurs over months to years
    - Often due to a chronic lung disease process

# CLASSIFICATION

- **The underlying issue**
- Hypoxemic respiratory failure (TYPE 1 )
  - Most common form of respiratory failure
  - Results from a ↓ ability to oxygenate the blood
- Hypercapnic respiratory failure (TYPE 2)

Results from a ↓ ability to eliminate carbon dioxide (CO<sub>2</sub>)

↓ pH of the blood → respiratory acidosis

# CLASSIFICATION

- **. Type 3 Respiratory Failure (Perioperative Respiratory Failure)**

This category refers to respiratory failure that occurs during or after surgery, particularly in the postoperative period. It is usually a combination of both hypoxemia and hypercapnia due to impaired respiratory mechanics.

- **D. Type 4 Respiratory Failure (Acid-Base Imbalance)**

This is a rare type of respiratory failure characterized by both respiratory failure and significant metabolic acidosis or alkalosis due to the body's failure to compensate for respiratory changes.

# **Etiology**

- Respiratory failure can occur if there is an abnormality with any component of the respiratory system.
  
- Components of the respiratory system include the
  - upper and lower respiratory tracts,
  - the central and peripheral nervous systems,
  - the chest wall and muscles of respiration

## Respiratory Failure

component

# Etiology of hypoxemic respiratory failure

- ✓ Right-to-left shunt:
  - ✓ [Pulmonary edema](#) (cardiogenic and noncardiogenic)
  - ✓ [Pneumonia](#)
  - ✓ Pulmonary hemorrhage
  - ✓ Aspiration
  - ✓ [Atelectasis](#)
  - ✓ ARDS
- ✓ V/Q mismatch:
  - ✓ [Pulmonary embolism](#)
  - ✓ [Asthma](#)
  - ✓ Chronic obstructive [pulmonary disease \(COPD\)](#)
  - ✓ [Cystic fibrosis](#)
  - ✓ Interstitial lung disease
  - ✓ [Pulmonary hypertension](#)
- ✓ Low inspired oxygen: high altitude
- ✓ Hypoventilation:
  - ✓ Sedative medications
  - ✓ Neuromuscular conditions

## Mechanisms, etiology, and management of acute hypoxemic respiratory failure

Cause of hypoxemia*	Definition	Etiologies	A-a gradient	PaCO <sub>2</sub>	Response to oxygen	Treatment
V/Q mismatch	<ul style="list-style-type: none"> <li>Imbalance of lung perfusion relative to ventilation: <ul style="list-style-type: none"> <li>Low V/Q – Regions underventilated relative to perfusion (<b>shunt</b> is extreme form of low V/Q mismatch; refer to below)</li> <li>High V/Q – Regions that are overventilated relative to perfusion (<b>dead space</b> is extreme form of high V/Q mismatch)</li> </ul> </li> </ul>	<ul style="list-style-type: none"> <li>Embolic disease (venous pulmonary embolism, fat embolism, amniotic fluid embolism, malignant cells)</li> <li>Pulmonary vascular disease (destroys capillary beds and limits perfusion to alveoli)</li> <li>Chronic obstructive lung disease/emphysema (destroys the pulmonary capillary-alveolar interface)</li> <li>Interstitial diseases (eg, pulmonary edema, pulmonary inflammation)</li> <li>Low flow cardiac output states</li> </ul>	High	Typically normal (unless associated with hypoventilation or significant increase in dead space)	Yes (unless due to shunt)	<ul style="list-style-type: none"> <li>Supplemental oxygen</li> <li>Treat underlying cause</li> </ul>
Right-to-left shunt	<ul style="list-style-type: none"> <li>Extreme form of low V/Q mismatch: <ul style="list-style-type: none"> <li>Anatomic (ie, mechanical shunt)</li> <li>Physiologic (ie, typically capillary shunt)</li> </ul> </li> </ul>	<ul style="list-style-type: none"> <li>Anatomic: <ul style="list-style-type: none"> <li>Cardiac shunt (eg, ASD, PFO, VSD)</li> <li>Intravascular shunt (pulmonary or other AVM, hepatopulmonary syndrome)</li> </ul> </li> <li>Physiologic: <ul style="list-style-type: none"> <li>Capillary shunt (eg, atelectasis, edema, pneumonia)</li> <li>Alveolar filling disorders (eg, fluid, hemorrhage, pus, cells, protein, lipid)</li> <li>Complete airway obstruction (including angioedema)</li> </ul> </li> </ul>	High	Normal	No	<ul style="list-style-type: none"> <li>Oxygen; however, it is frequently minimally responsive or unresponsive to oxygen</li> <li>Treat underlying cause</li> </ul>
Hypoventilation	<ul style="list-style-type: none"> <li>Reduced minute ventilation "can't breathe, won't breathe, can't breathe enough"<sup>†</sup></li> </ul>	<ul style="list-style-type: none"> <li>Central neurologic disease (eg, stroke, sedation, hypothyroidism)</li> <li>Respiratory neuromuscular and chest wall diseases (eg, cervical-spine or phrenic nerve injury, Guillain-Barré syndrome, bilateral diaphragmatic weakness)</li> <li>Airway/alveolar disease (acute exacerbation of COPD, asthma, ILD)</li> </ul>	Normal	Elevated	Yes	<ul style="list-style-type: none"> <li>Supplemental oxygen (oxygen will improve oxygenation but will <b>not</b> resolve hypercapnia)</li> <li>Increase minute ventilation (eg, noninvasive ventilation or invasive ventilation)</li> <li>Treat underlying cause</li> </ul>
Diffusion defect	<ul style="list-style-type: none"> <li>Impairment of gas exchange between alveoli and pulmonary capillaries</li> <li>Often overlaps with shunt or V/Q mismatch pathophysiology</li> </ul>	<ul style="list-style-type: none"> <li>ILD</li> <li>Lung resection</li> <li>Emphysema</li> <li>Pulmonary vascular disease</li> </ul>	High (occasionally normal)	Normal	Yes	<ul style="list-style-type: none"> <li>Supplemental oxygen</li> <li>Treat underlying cause</li> </ul>
Reduced P <sub>I</sub> O <sub>2</sub>	<ul style="list-style-type: none"> <li>Reduced P<sub>I</sub>O<sub>2</sub><sup>Δ</sup></li> </ul>	<ul style="list-style-type: none"> <li>Sudden change in elevation or new altitude</li> <li>Reduction in pressure during air travel in aircraft</li> </ul>	Normal	Normal or low (if hyperventilation present)	Yes	<ul style="list-style-type: none"> <li>Descent if altitude is the cause</li> <li>Supplemental oxygen</li> <li>Consider acetazolamide</li> </ul>
Increased oxygen extraction	<ul style="list-style-type: none"> <li>Reduced mixed venous oxygen content of blood returning to the right side of the heart</li> </ul>	<ul style="list-style-type: none"> <li>Decreased cardiac output</li> <li>Anemia</li> <li>Hypermetabolism (eg, fever, sepsis, hyperthyroidism, burns, trauma)</li> </ul>	High	Normal	Yes	<ul style="list-style-type: none"> <li>Supplemental oxygen</li> <li>Treat underlying cause</li> </ul>

A-a gradient: alveolar-arterial gradient; PaCO<sub>2</sub>: arterial carbon dioxide tension; V/Q: ventilation/perfusion; ASD: atrial septal defect; PFO: patent foramen ovale; VSD: ventricular septal defect; AVM: arteriovenous malformation; COPD: chronic obstructive pulmonary disease; ILD: interstitial lung disease; P<sub>I</sub>O<sub>2</sub>: inspired oxygen tension.

\* Rare causes of hypoxemia include hemoglobinopathies, cyanide toxicity, methemoglobinemia, and leukocyte larceny.

<sup>†</sup> Refer to UpToDate content on hypercapnia.

# Etiology of hypercapnic respiratory failure

## ➤ Diminished respiratory drive:

- Sedative medications ([opioids](#), [benzodiazepines](#))
- [Brain](#) stem lesions (affecting the central respiratory center)
- Multiple [sclerosis](#) (bulbar dysfunction leading to central respiratory drive depression)
- [Hypothermia](#)

## ➤ Impaired respiratory muscle function:

- Guillain–Barré syndrome
- [Myasthenia gravis](#)
- Amyotrophic lateral [sclerosis](#)
- Multiple [sclerosis](#)
- [Botulism](#)
- [Tetanus](#)
- [Spinal cord](#) lesions
- Muscle [fatigue](#) (seen with hypoxemic respiratory failure)
- [Malnutrition](#)
- [Myopathy](#)

# Etiology of hypercapnic respiratory failure

- Airway obstruction:
  - COPD
  - Asthma
  - Obstructive sleep apnea
  - Cystic fibrosis
  - Airway edema
- Diminished lung elasticity/compliance:
  - Alveolar edema
  - Pneumonia
  - Atelectasis
  - ARDS
- Diminished chest wall elasticity:
  - Pleural effusion
  - Obesity
  - Kyphoscoliosis
  - Abdominal distention
  - Pneumothorax

### Mechanism and etiologies of hypercapnia

Mechanism	Etiologies			
<b>Decreased minute ventilation (global hypoventilation; extra pulmonary causes)</b>

This is a comprehensive list of etiologies of hypercapnia that are not listed in order of which is more or less common. Decreased mechanical ventilation can also cause hypercapnic respiratory acidosis (eg, permissive hypercapnia). Importantly, any factor that limits the mechanical function of the ventilatory pump (such as airway obstruction or weak muscles), when combined with a gas exchange abnormality (increased physiological dead space), may lead to hypercapnia. For further details regarding the mechanisms that underlie these pathologies, please refer to the UpToDate topic on mechanisms, causes, and effects of hypercapnia.

\* Hyperthyroidism is also a rare cause of respiratory muscle weakness.  
† Injury or disease process needs to be between cervical spine level 3 and 5 (C3 to 5) for clinically significant diaphragmatic paresis/paralysis to occur.  
‡ Hypermagnesemia, hypokalemia, and hypercalcemia can also cause respiratory muscle weakness and contribute to hypercapnia.  
‡ Upper airway disorders are rare causes of hypercapnia. They either diminish total ventilation or lead to dynamic hyperinflation and reduced tidal volume while simultaneously causing increased work of breathing and carbon dioxide production.

### Respiratory pathway affecting carbon dioxide elimination

Central nervous system ↓	<b>"Won't breathe"</b>
Peripheral nervous system ↓	
Respiratory muscles ↓	
Chest wall and pleura ↓	
Upper airway ↓	
Lungs	<b>Abnormal gas exchange: "Can't breathe enough"</b>

**Decreased minute ventilation (global hypoventilation; extra pulmonary causes)**

Decreased central respiratory drive

- Sedative overdose (eg, narcotic or benzodiazepine, some anesthetics, tricyclic antidepressants)
- Encephalitis
- Stroke
- Central and obstructive sleep apnea
- Obesity hypoventilation
- Congenital central alveolar hypoventilation
- Brainstem disease
- Metabolic alkalosis
- Hypothyroidism\*
- Hypothermia
- Starvation

Decreased respiratory neuromuscular or thoracic cage function

**Primary spinal cord/lower motor neuron/muscle disorders**

- Cervical spine injury or disease (eg, trauma syringomyelia)<sup>†</sup>
- Amyotrophic lateral sclerosis
- Poliomyelitis
- Guillain-Barré syndrome
- Phrenic nerve injury
- Critical illness polymyoneuropathy
- Myasthenia gravis
- Muscular dystrophy
- Polymyositis
- Tetanus
- Transverse myelitis (eg, multiple sclerosis)
- Tick paralysis
- Acute intermittent porphyria

**Thoracic cage disorders**

- Kyphoscoliosis
- Thoracoplasty
- Flail Chest
- Ankylosing spondylitis
- Pectus excavatum
- Fibrothorax

**Metabolic disorders<sup>Δ</sup>**

- Hypophosphatemia
- Hypomagnesemia
- Hypothyroidism
- Hyperthyroidism

**Toxins, poisoning, drugs**

- Tetanus
- Dinoflagellate poisoning
- Shellfish poisoning (red tide)
- Ciguatera poisoning
- Botulism
- Organophosphates
- Succinylcholine and neuromuscular blockade

respiratory muscle fatigue

**Increased dead space (gas exchange abnormalities; pulmonary parenchymal causes or airway disorders)**

Anatomic

- Short shallow breathing

Physiologic

- Pulmonary embolism (usually severe)
- Pulmonary vascular disease (usually severe)
- Dynamic hyperinflation (eg, upper and lower airway disorders including chronic obstructive pulmonary disease, severe asthma)
- Endstage interstitial lung disease

**Increased carbon dioxide production**

### Increased carbon dioxide production

- Fever
- Thyrotoxicosis
- Increased catabolism (sepsis, steroids)
- Overfeeding
- Metabolic acidosis
- Exercise

### Multifactorial

#### Upper airway disorder <sup>◇</sup>

- Severe laryngeal or tracheal disorders (stenosis/tumors/angioedema/tracheomalacia)
- Vocal cord paralysis
- Epiglottitis
- Foreign body aspiration
- Retropharyngeal disorders
- Obstructive goiter

# Pathophysiologic causes of Acute RF

- Hypoventilation
- V/Q mismatch
- Shunt
- Diffusion abnormality

# Hypoventilation

- Occurs when ventilation  $\downarrow$  4-6 l/min
- Causes
  - Depression of CNS from drugs
  - Neuromuscular disease of respiratory muscles
- $\uparrow$ PaCO<sub>2</sub> and  $\downarrow$ PaO<sub>2</sub>
- Alveolar –arterial PO<sub>2</sub> gradient is normal
- COPD

## V/Q mismatch

- Most common cause of hypoxemia
- Caused by
  - ventilation of non-perfused alveoli. (high V/Q ratio)
  - Perfusion to non-ventilated alveoli (Low V/Q ratio)
- Admin. of 100% O<sub>2</sub> eliminate hypoxemia

- Ventilation-to-perfusion inequality
- A mismatch between [ventilation](#) and perfusion occurs from a disease process resulting in either:
- Low V/Q ratio:
  - May occur from:
    - Diminished oxygen entry into [alveoli](#) with normal [blood flow](#)
    - Overperfusion of [alveoli](#) with normal [ventilation](#) (e.g., diversion of [blood flow](#))
  - Results in:
    - [Hypoxemia](#)
    - [Hypercapnia](#)
- High V/Q ratio:
  - Results from diminished [blood flow](#) to [alveoli](#) with normal [ventilation](#)
  - [Ventilation](#) is wasted.
  - Must be severe for [gas exchange](#) to be affected
- Note: [100% oxygen](#) administration can correct oxygenation in V/Q mismatch.

# Shunt

- Right-to-left shunt
- Blood is shunted from the right side of the heart to the left side without undergoing oxygenation.
- Deoxygenated blood mixes with oxygenated blood → ↓ arterial pressure of O<sub>2</sub>
- This can be caused by:
  - Cardiac shunting (e.g., [congenital](#) malformations of the heart that allow blood to bypass the respiratory system)
  - Pulmonary shunting (e.g., fluid fills the [alveoli](#), preventing oxygen [diffusion](#))

## Shunt

- The deoxygenated blood bypasses the ventilated alveoli and mixes with oxygenated blood → hypoxemia
- Persistent of hypoxemia despite 100% O<sub>2</sub> inhalation
- Hypercapnia occur when shunt is excessive > 60%

# Causes of Shunt

- Intra-cardiac
  - Fallot's tetralogy
  - Eisenmenger's syndrome
  
- Pulmonary
  - A/V malformation
  - Pneumonia
  - Pulmonary edema
  - Atelectasis/collapse
  - Pulmonary Hge
  - Pulmonary contusion

# Diffusion abnormality

- Less common
- Due to
  - abnormality of the alveolar membrane
  - ↓ the number of the alveoli
- Causes
  - ARDS
  - Fibrotic lung disease

# Clinical Presentation

# General signs and symptoms

- Vitals:
  - Tachypnea
  - Tachycardia
  - Low transcutaneous oxygen saturation in hypoxemic respiratory failure (late sign)
- Dyspnea
- Increased work of breathing and use of accessory muscles of breathing
- Diaphoresis
- Altered mental status:
  - Restlessness and anxiety
  - Confusion
  - Somnolence
  - Coma

## *Hypoxemic Respiratory Failure (Type 1):*

- **Dyspnea:** Shortness of breath, especially with exertion, or even at rest if severe.
- **Cyanosis:** Bluish discoloration of the skin, lips, or nail beds due to low oxygen levels.
- **Tachypnea:** Increased respiratory rate as the body attempts to compensate for low oxygen levels.
- **Use of Accessory Muscles:** This is a sign of increased work of breathing as the body attempts to recruit additional muscles to aid in ventilation.
- **Confusion/Agitation:** Decreased oxygen supply to the brain can cause cognitive impairment and agitation.
- **Fatigue:** Severe cases can lead to exhaustion as the body's energy is used to compensate.

# Hypercapnia Respiratory Failure (Type 2)

- ❑ **Dyspnea:** More often with shallow breathing.
- ❑ **Headache:** Elevated CO<sub>2</sub> levels lead to vasodilation in the brain, causing increased intracranial pressure.
- ❑ **Drowsiness or Confusion:** Hypercapnia can depress the CNS, leading to confusion or even coma in severe cases.
- ❑ **Tachypnea:** Initially, the body tries to compensate by increasing the breathing rate to expel CO<sub>2</sub>.
- ❑ **Peripheral Edema:** If associated with chronic conditions like COPD or heart failure

# Laboratory assessment

- ABG analysis
- Lung function
- Vitalogram(pulmonary function tests)
- Chest Radiograph
- ECG
- Echocardiography
- CBC and blood cultures.

-

# Arterial blood gas

- Diagnosis
- An arterial blood gas (ABG) analysis is required in the diagnosis of respiratory failure. It measures and calculates components in arterial blood:
- **Measured:**
  - pH
  - Partial pressure of oxygen ( $\text{PaO}_2$ )
  - Partial pressure of  $\text{CO}_2$  ( $\text{PaCO}_2$ )
- **Calculated:**
  - Bicarbonate ( $\text{HCO}_3$ )
  - Base excess
  - Oxygen saturation ( $\text{SaO}_2$ )

**PH**      **acidosis**      <      **7.4**      >      **alkalosis**

<b>PH</b>	<b>7.35 - 7.45</b>
<b>PaCo2</b>	<b>35 - 45</b>
<b>HCo3</b>	<b>22 - 28</b>

**Respiratory**

**Metabolic**

**R** **Respiratory**

**O** **Opposite**

**M** **Metabolic**

**E** **Equal**

**PH** ↑    **PCo2** ↓    **Alkalosis**

**PH** ↓    **PCo2** ↑    **Acidosis**

**PH** ↑    **HCo3** ↑    **Alkalosis**

**PH** ↓    **HCo3** ↓    **Acidosis**

# ARTERIAL BLOOD GAS INTERPRETATION

## 6-step approach:

- **Step 1:** Assess the internal consistency of the values using the Henderseon-Hasselbach equation:  $[H^+] = 24(P_aCO_2) / [HCO_3^-]$
- **Step 2** Is there alkalemia or acidemia present? pH < 7.35 acidemia  
pH > 7.45 alkalemia
- **Step 3** Is the disturbance respiratory or metabolic?
- **Step 4** Is there appropriate compensation for the primary disturbance? Usually, compensation does not return the pH to normal (7.35 – 7.45).
- **Step 5:** Calculate the anion gap (if a metabolic acidosis exists):  $AG = [Na^+] - ([Cl^-] + [HCO_3^-]) - 12 \pm 2$  (normaly 12)
- **Step 6:** If an increased anion gap is present, assess the relationship between the increase in the anion gap and the decrease in  $[HCO_3^-]$ .
  - ✓ Assess the ratio of the change in the anion gap ( $\Delta AG$ ) to the change in  $[HCO_3^-]$  ( $\Delta[HCO_3^-]$ ):  $\Delta AG / \Delta[HCO_3^-]$
  - ✓ *This ratio should be between 1.0 and 2.0 if an uncomplicated anion gap metabolic acidosis is present*

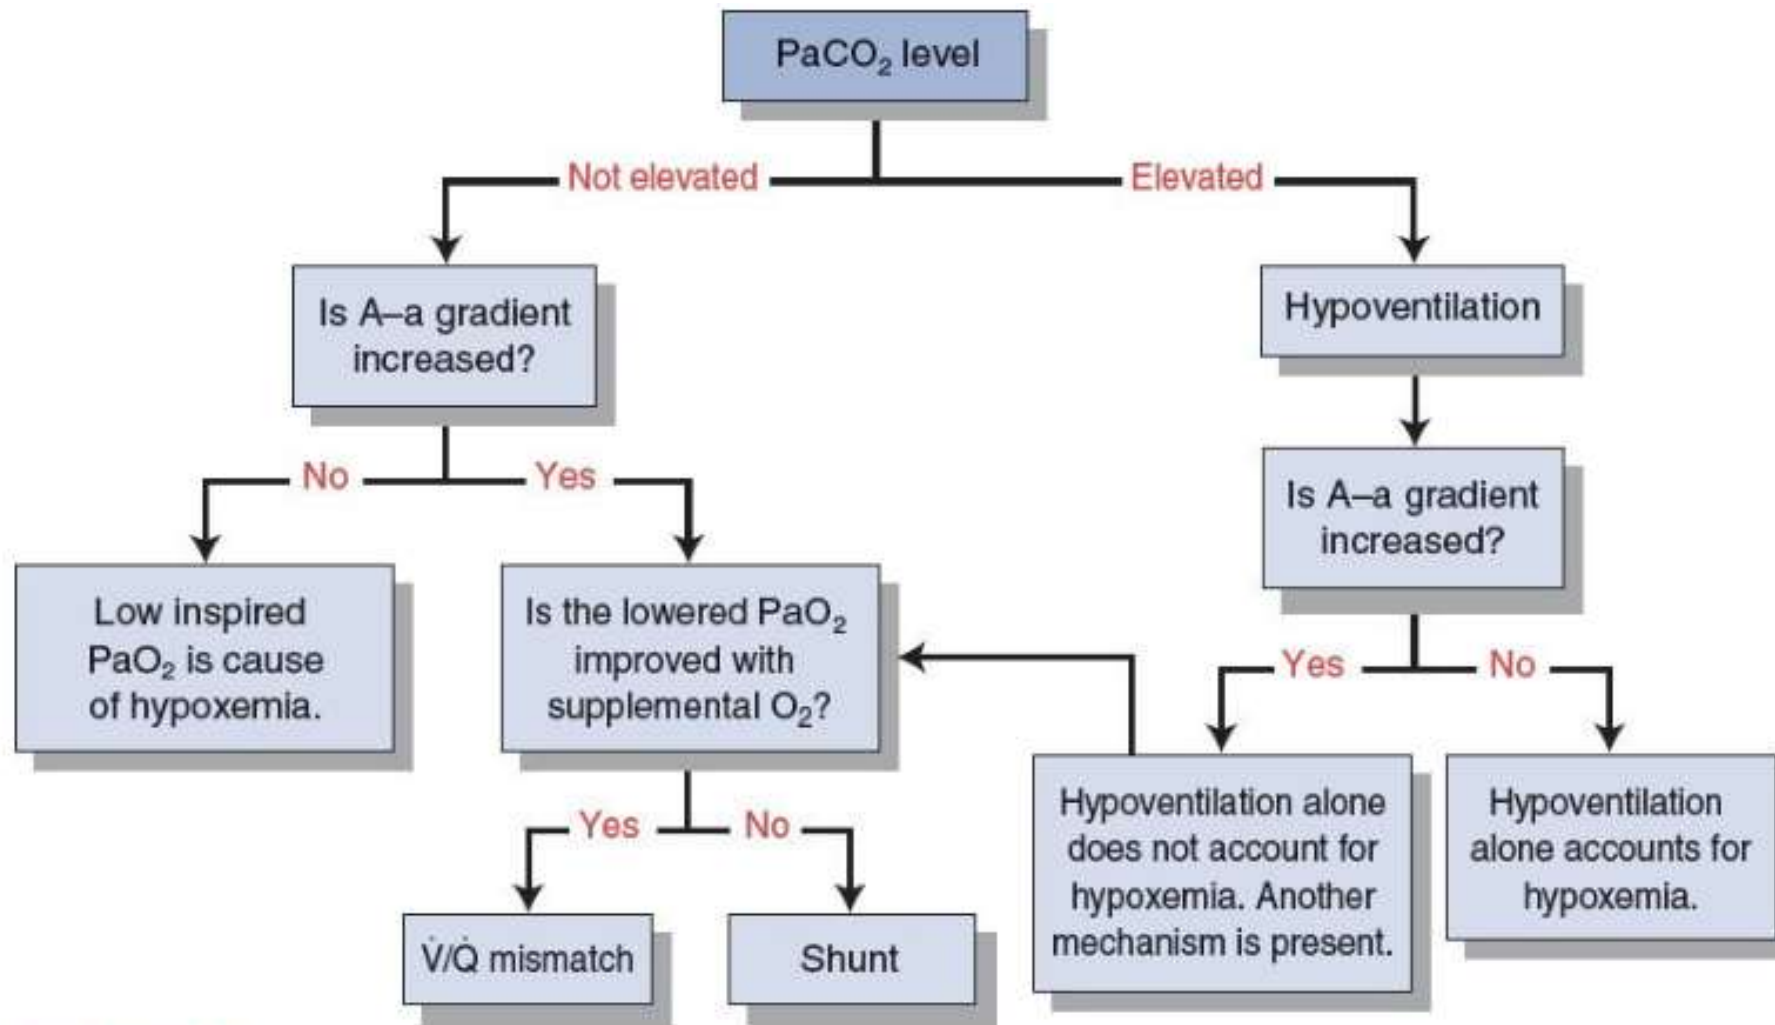

## ARTERIAL BLOOD GAS INTERPRETATION

1° DISORDER	pH	P <sub>a</sub> CO <sub>2</sub>	[HCO <sub>3</sub> <sup>-</sup> ]	COMPENSATION
<b>AG/non-AG Metabolic Acidosis</b>	↓	↓ (2°)	↓ (1°)	$P_aCO_{2, \text{expect}} = 1.5 [HCO_3^-] + 8 \pm 2$ If $P_aCO_{2, \text{actual}} < P_aCO_{2, \text{expect}}$ also 1° respiratory alkalosis If $P_aCO_{2, \text{actual}} > P_aCO_{2, \text{expect}}$ also 1° respiratory acidosis
<b>AG Acidosis "Delta/Delta"</b>	For AG metabolic acidosis, calculate $\Delta AG / \Delta[HCO_3^-] = (AG - 12) / (24 - [HCO_3^-])$ if < 0.8, non-AG acidosis; if > 2, metabolic alkalosis			
<b>Metabolic Alkalosis</b>	↑	↑ (2°)	↑ (1°)	$P_aCO_2 = 0.7 \times [HCO_3^-] + 20 \pm 5$ If $P_aCO_{2, \text{actual}} < P_aCO_{2, \text{expect}}$ also 1° respiratory alkalosis If $P_aCO_{2, \text{actual}} > P_aCO_{2, \text{expect}}$ also 1° respiratory acidosis
<b>Respiratory Acidosis</b>	↓	↑ (1°)	↑ (2°)	For each ↑ 10 mmHg in P <sub>a</sub> CO <sub>2</sub> Acute: ↑ [HCO <sub>3</sub> <sup>-</sup> ] 1 mmol/L and ↓ pH 0.08 Chronic: ↑ [HCO <sub>3</sub> <sup>-</sup> ] 4 mmol/L and ↓ pH 0.03
<b>Respiratory Alkalosis</b>	↑	↓ (1°)	↓ (2°)	For each ↓ 10 mmHg in P <sub>a</sub> CO <sub>2</sub> Acute: ↓ [HCO <sub>3</sub> <sup>-</sup> ] 2 mmol/L and ↑ pH 0.08 Chronic: ↓ [HCO <sub>3</sub> <sup>-</sup> ] 5 mmol/L and ↑ pH 0.03
Primary disorder (1°), compensation (2°); arrows relative to "normal" baseline values: pH 7.35 - 7.45, P <sub>a</sub> CO <sub>2</sub> 35 - 45 mmHg and [HCO <sub>3</sub> <sup>-</sup> ] 22 - 26 mEq/L				

# Alveolar–arterial gradient

- The alveolar–arterial (A-a) gradient can be used to help in understanding the potential underlying etiology
- Defined as the difference between the oxygen concentration in the [alveoli](#) (PAO<sub>2</sub>) and arterial blood (PaO<sub>2</sub>):
  - A-a gradient = PAO<sub>2</sub> – PaO<sub>2</sub>
  - PAO<sub>2</sub>: calculated from the alveolar gas equation
  - PaO<sub>2</sub>: measured in an ABG
- Interpretation:
  - Normal: 5–10 mmHg
  - Increased in etiologies that cause:
    - Right-to-left shunting
    - V/Q mismatch

- $PAO_2 = FiO_2 (PB - P_{water}) - PaCO_2/0.8,$ 
  - ✓  $PAO_2$  = Alveolar partial pressure of oxygen
  - ✓  $FiO_2$  = Fraction of inspired oxygen
  - ✓  $PB$  = Barometric (Atmospheric) pressure
  - ✓  $P_{water}$  = Vapor pressure of water at body temperature ( $37^\circ C$ )=47 mmHg
  - ✓  $PaCO_2$  = Partial pressure of arterial carbon dioxide

**2.12**

**Evaluation of a patient with hypoxemia.**

# Chest X-ray/CT Scan

Provides imaging of the lungs to help identify conditions such as

- pneumonia
- pulmonary edema
- Pneumothorax
- Pleural effusion
- COPD
- ARDS

# Hyperinflated Lungs : COPD

Pleural effusion

ARDS

Pneumonia

Pneumothorax

- **Pulmonary Function Tests:**

- Useful for assessing lung function, particularly in chronic conditions like COPD and asthma.

- **Electrocardiogram (ECG):**

- May help rule out cardiac causes, such as arrhythmias or ischemia, which may lead to respiratory failure.

- **Pulse Oximetry:**

- Non-invasive monitoring of oxygen saturation. While helpful for continuous monitoring, it

THE UNIVERSITY OF  
JORDAN

# Management of Respiratory Failure

# Management of Respiratory Failure Principles

- Hypoxemia may cause death in RF
- Primary objective is to reverse and prevent hypoxemia
- Secondary objective is to control PaCO<sub>2</sub> and respiratory acidosis
- Treatment of underlying disease
- Patient's CNS and CVS must be monitored and treated

# Oxygen Therapy

- Supplemental O<sub>2</sub> therapy essential
- titration based on SaO<sub>2</sub>, PaO<sub>2</sub> levels and PaCO<sub>2</sub>
- Goal is to prevent tissue hypoxia
- Increase arterial PaO<sub>2</sub> > 60 mmHg (SaO<sub>2</sub> > 90%) or venous SaO<sub>2</sub> > 60%
- O<sub>2</sub> dose either flow rate (L/min) or FiO<sub>2</sub> (%)

## OXYGEN DELIVERY SYSTEMS

**Device: Nasal Cannula**  
**Flow: 1 - 6 L/min**  
**FiO<sub>2</sub>: 25 - 40%**  
**(~4%/L of flow)**

**Device: Face Mask**  
**Flow: 5 - 10 L/min**  
**FiO<sub>2</sub>: 40 - 60%**

**Device: Face Tent**  
**Flow: 10 - 15 L/min**  
**FiO<sub>2</sub>: ~40%**

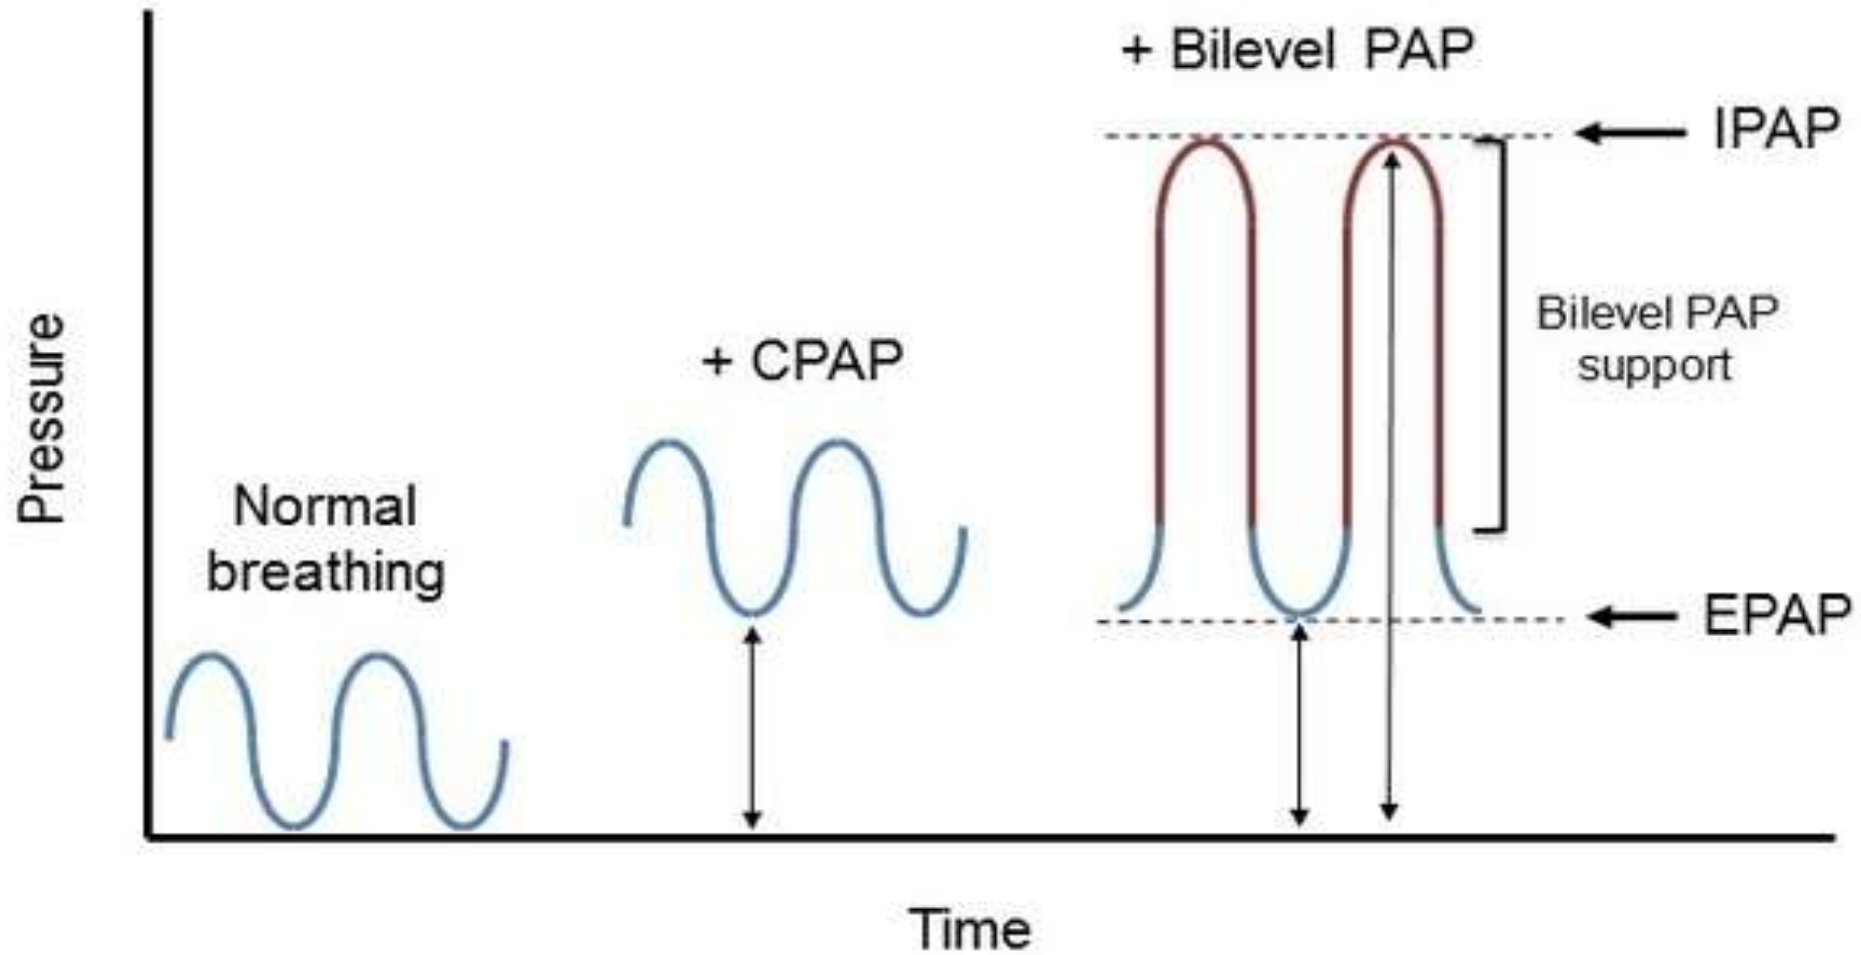

**Device: Venturi Mask**  
**Flow: 2 - 15 L/min**  
**(based on valve)**  
**FiO<sub>2</sub>: 24 - 60%**  
**(precisely controlled)**

**Device: Non-Rebreather**  
**Flow: 10 - 15 L/min**  
**FiO<sub>2</sub>: 80 - 95%**

**Device: High Flow  
Nasal Cannula**  
**Flow: up to 60 L/min**  
**FiO<sub>2</sub>: 21 - 100%**

# If noninvasive devices failed

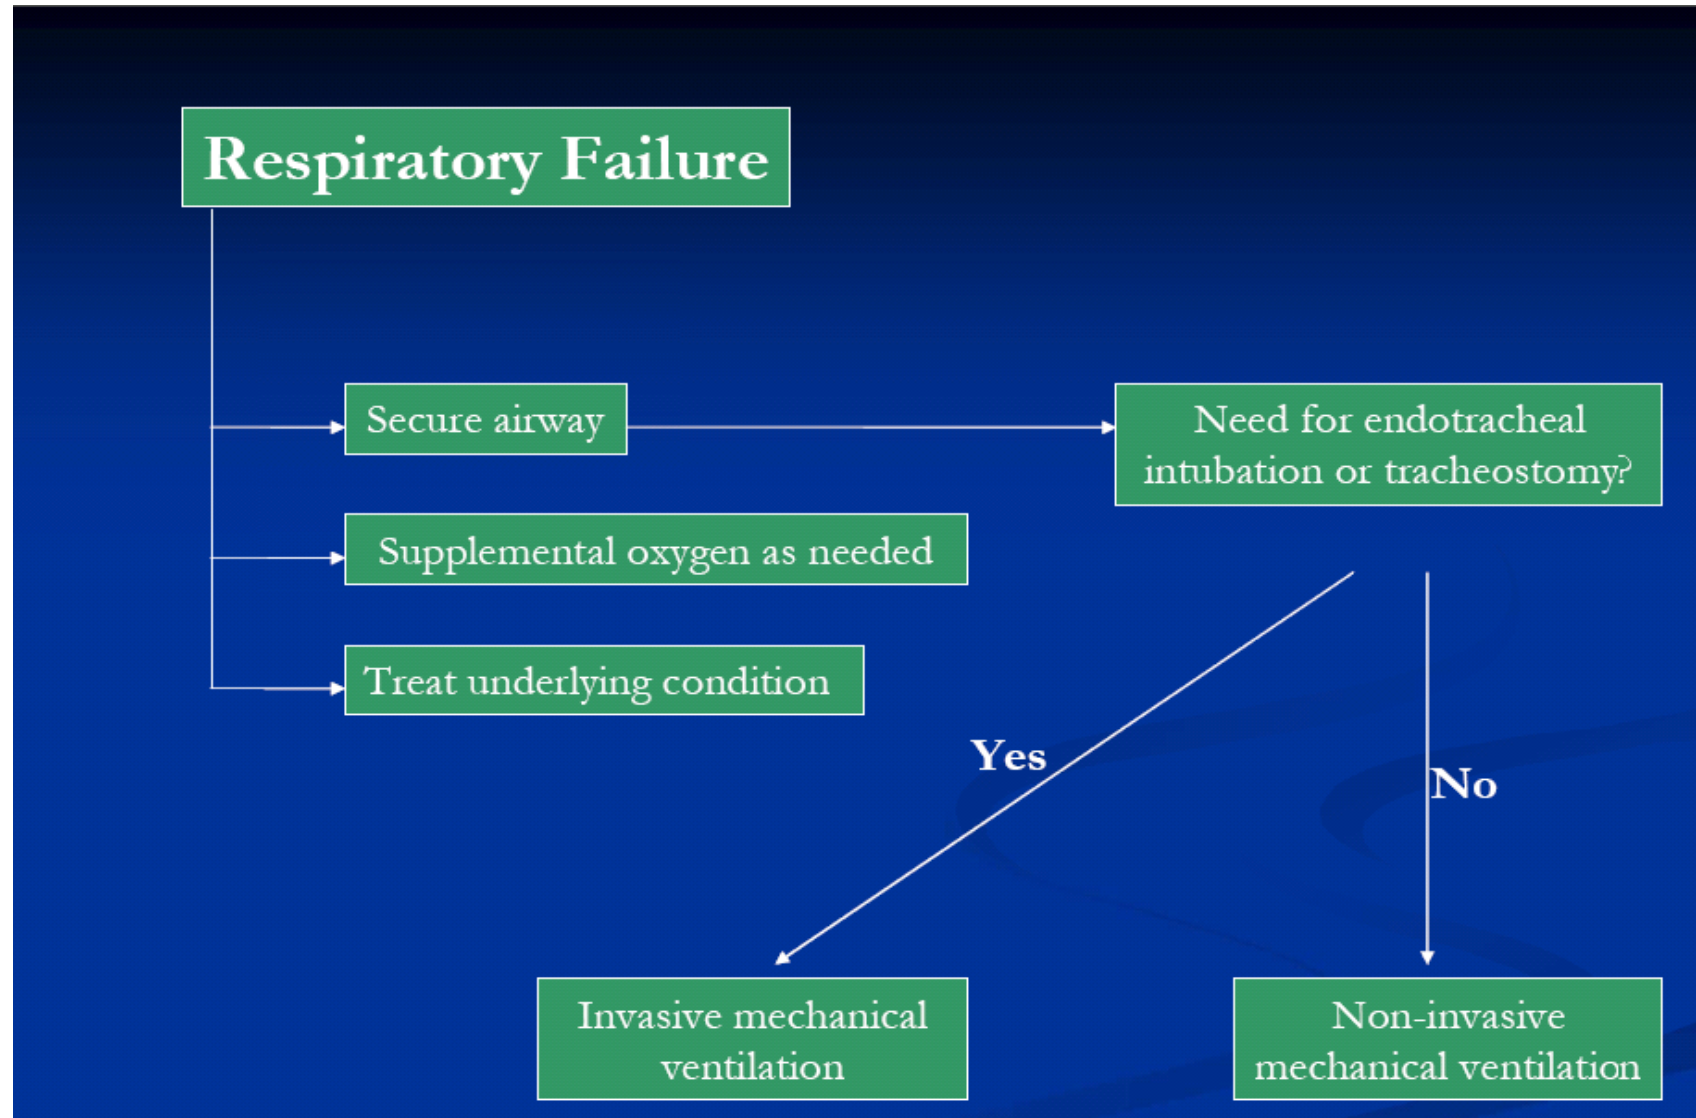

Correct hypoxemia  
Correct acute respiratory acidosis  
Resting of ventilatory muscles

# Indications for Mechanical Ventilation Include the Following

- Apnea with respiratory arrest
- Tachypnea with respiratory rate >30 breaths per minute
- Disturbed conscious level or coma
- Respiratory muscle fatigue
- Hemodynamic instability
- Failure of supplemental oxygen to increase PaO<sub>2</sub> to 55 to 60 mmHg
- Hypercapnia with arterial pH less than

# ACUTE RESPIRATORY FAILURE

# Complications of ARF

- **Pulmonary**
  - Pulmonary embolism
  - barotrauma
  - pulmonary fibrosis (ARDS)
  - Nosocomial pneumonia
- **Cardiovascular**
  - Hypotension, ↓COP
  - Arrhythmia
  - MI, pericarditis
- **GIT**
  - Stress ulcer, ileus, diarrhea, hemorrhage
- **Infections**
  - Nosocomial infection
  - Pneumonia, UTI, catheter related sepsis
- **Renal**
  - ARF (hypoperfusion, nephrotoxic drugs)
  - Poor prognosis
- **Nutritional**
  - Malnutrition, diarrhea hypoglycemia, electrolyte disturbances

## Prognosis of ARF

- Respiratory failure is a syndrome caused by a multitude of pathological states; therefore, the prognosis of this disease process is difficult to ascertain.
- In 2017, in the United States of America, however, the in-hospital respiratory failure mortality rate was 12%.
- In-hospital mortality rates for patients requiring intubation with mechanical ventilation for asthma exacerbation, acute exacerbation of chronic obstructive pulmonary disease, and pneumonia were found to be 9.8%, 38.3%, and 48.4%, respectively.
- Lastly, the in-hospital mortality rate for acute respiratory distress syndrome was found to be 44.3%
